17.12 Connecting Analytic and Textual Markup

In chapters *18. Simple Analytic Mechanisms* and *19. Feature Structures* and elsewhere, provision is made for analytic and interpretive markup to be represented outside of textual markup, either in the same document or in a different document. The elements in these separate domains can be connected, either with the pointing attributes *ana* (for *analysis*) and *inst* (for *instance*), or by means of <link> and <linkGrp> elements. Numerous examples are given in these chapters.

Another more specific form of annotation is available through the TEI <ruby> element and its children, described in detail in *3.4.2. Ruby Annotations*.

17.13 Module for Linking, Segmentation, and Alignment

The module described in this chapter makes available the following components:

Module linking: Linking, segmentation, and alignment

- *Elements defined*: ab alt altGrp anchor annotation join joinGrp link linkGrp listAnnotation seg standOff timeline when
- *Classes defined*: att.global.linking

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

18 Simple Analytic Mechanisms

This chapter describes a module for associating simple analyses and interpretations with text elements. We use the term *analysis* here to refer to any kind of semantic or syntactic interpretation which an encoder wishes to attach to all or part of a text. Examples discussed in this chapter include familiar linguistic categorizations (such as 'clause', 'morpheme', 'part-of-speech' etc.) and characterizations of narrative structure (such as 'theme', 'reconciliation' etc.). The mechanisms presented in this chapter are simpler but less powerful than those described in chapter *19. Feature Structures*.

Section *18.1. Linguistic Segment Categories* introduces elements which can be used to characterize text segments according to the familiar linguistic categories of *sentence* or *s-unit*, *clause*, *phrase*, *word*, *morpheme*, *character*, and *punctuation mark*. These elements represent special cases of the generic <seg> element described in section *17.3. Blocks, Segments, and Anchors*.

Section *18.2. Global Attributes for Simple Analyses* introduces an additional global attribute which allows passages of text to be associated with specialized elements representing their interpretation. These 'interpretative' elements (and <interp>) are described in detail in section *18.3. Spans and Interpretations*. They allow the encoder to specify an analysis as a series of names and associated values,[109] each such pair being linked to one or more stretches of text, either directly, in the case of spans, or indirectly, in the case of interpretations.

Finally section *18.4. Linguistic Annotation* revisits the topic of linguistic analysis, and illustrates how these interpretative mechanisms may be used to associate simple linguistic analysis with text segments.

18.1 Linguistic Segment Categories

In this section we introduce specialized *linguistic segment category* elements which may be used to represent the segmentation of a text into the traditional linguistic categories of *sentence*, *clause*, *phrase*, *word*, *morpheme*, *characters*, and *punctuation marks*.

18.1.1 Words and Above

Although different languages have very different rules about what constitutes a 'word' or a 'sentence', these remain generally useful concepts. In this section we discuss elements provided for marking up linguistic units down to the word level, however defined.

`<s>` (s-unit) contains a sentence-like division of a text.

`<cl>` (clause) represents a grammatical clause.

`<phr>` (phrase) represents a grammatical phrase.

`<w>` (word) represents a grammatical (not necessarily orthographic) word.

As members of the `att.segLike` class, these elements all share the following attribute:

`att.segLike` provides attributes for elements used for arbitrary segmentation.

`@function` (function) characterizes the function of the segment.

They also share attributes from `att.typed`:

`att.typed` provides attributes that can be used to classify or subclassify elements in any way.

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

`@subtype` (subtype) provides a sub-categorization of the element, if needed.

These elements are also all members of the `model.segLike` class, which is a subclass of `model.phrase`. They may thus appear anywhere that text is permitted within a document, when the module defined by this chapter is included in a schema.

The <w> and <pc> elements belong to the `att.linguistic` class, which supplies attributes that may be used for lightweight linguistic annotation (see section *18.4.2. Lightweight Linguistic Annotation* below):

`att.linguistic` provides a set of attributes concerning linguistic features of tokens, for usage within token-level elements, specifically <w> and <pc> in the analysis module.

`@lemma` provides a lemma (base form) for the word, typically uninflected and serving both as an identifier (e.g. in dictionary contexts, as a headword), and as a basis for potential inflections.

[109] Or, as they are widely known, *attribute-value pairs*; this term should not be confused, however, with XML attributes and their values, which are similar in concept but distinct in their formal definitions.

`@lemmaRef` provides a pointer to a definition of the lemma for the word, for example in an online lexicon.

`@pos` (part of speech) indicates the part of speech assigned to a token (i.e. information on whether it is a noun, adjective, or verb), usually according to some official reference vocabulary (e.g. for German: STTS, for English: CLAWS, for Polish: NKJP, etc.).

`@msd` (morphosyntactic description) supplies morphosyntactic information for a token, usually according to some official reference vocabulary (e.g. for German: STTS-large tagset; for a feature description system designed as (pragmatically) universal, see Universal Features).

`@join` when present, provides information on whether the token in question is adjacent to another, and if so, on which side.

Additionally, these elements also have access to the `att.lexicographic.normalized` class, which supplies the attributes *norm* and *orig*: the former for handling normalization/regularization at the word level, the latter providing the original form if the element content is modernized or regularized. Note that these attributes are a local (word-level) alternative to the robust mechanism that uses the <choice>, <orig>, and <reg> elements, discussed in section *3.5.2. Regularization and Normalization* and in chapter *13. Critical Apparatus*. The <choice>-based mechanism is the default descriptive device, while the *norm* and *orig* attributes are used to handle a subset of normalizations in linguistic contexts where a single sequence of tokens is a priority, for example in historical corpora subject to linguistic analysis. It needs to be stressed that the simplified attribute-based mechanism is not meant to be used for editorial interventions. [110]

The <s> element may be used simply to segment a text end-to-end into a series of non-overlapping segments, referred to here and elsewhere as *s-units*, or *sentences*.

```
<p>
  <s>Nineteen fifty-four, when I was eighteen years old,
     is held to be a crucial turning point in the history of
     the Afro-American — for the U.S.A. as a whole — the
     year segregation was outlawed by the U.S. Supreme Court.</s>
  <s>It was also a crucial year for me because on June 18,
     1954, I began serving a sentence in state prison for
     possession of marijuana.</s>
</p>
```

The <s> element is more restricted both in its content and its usage than the generic <seg> element. The <seg> unit may contain anything which can appear within a paragraph: thus it may be used to enclose members of the `model.inter` class (such as <bibl> or <list>) as well as other phrase elements; the <s> unit may only contain phrase-level elements or text. Also, unlike <seg> elements, <s> elements should not be nested within each other.[111] The <seg> element is intended for use as a generic segmentation element, the specific function of which may be indicated by its *type* attribute; the other members of the class are more specialized. Thus, the <s>, <cl>, and <phr> elements may be thought of as equivalent to <seg type="s-unit">, <seg type="clause"> and <seg type="phrase">, respectively, but with the above-mentioned restrictions.

The <s> element may be further subdivided into *clauses*, marked with the <cl> element, as in the following example:

```
<p>
  <s>
    <cl>It was about the beginning of September, 1664,
    <cl>that I, among the rest of my neighbours,
           heard in ordinary discourse
      <cl>that the plague was returned again to Holland; </cl>
      </cl>
```

[110] The `att.lexicographic.normalized` class is also used in dictionary entries, as discussed in chapter *10. Dictionaries*.

[111] Neither this constraint, nor the requirement that the whole of the text be segmented by <s> elements is required by the TEI Guidelines.

```
    </cl>
    <cl>for it had been very violent there, and particularly at
        Amsterdam and Rotterdam, in the year 1663, </cl>
    <cl>whither, <cl>they say,</cl> it was brought,
    <cl>some said</cl> from Italy, others from the Levant, among some goods
    <cl>which were brought home by their Turkey fleet;</cl>
    </cl>
    <cl>others said it was brought from Candia;
        others from Cyprus. </cl>
  </s>
  <s>
    <cl>It mattered not <cl>from whence it came;</cl>
    </cl>
    <cl>but all agreed <cl>it was come into Holland again.</cl>
    </cl>
  </s>
</p>
```

Clauses may be further divided into <phr> elements in the same way. A text may be segmented directly into clauses, or into phrases, with no need to include segmentation at a higher level as well.

For verse texts, the overlapping of metrical and syntactic structure requires that special care be given to representing both using an element hierarchy. One simple approach is to split the syntactic phrases into fragments when they cross verse boundaries, reuniting them with the *part* attribute:

```
<div  type="stanza">
  <l>
    <cl  part="I">Tweedledum and Tweedledee</cl>
  </l>
  <l>
    <cl  part="F">Agreed to have a battle;</cl>
  </l>
  <l>
    <cl  part="I">For Tweedledum said <cl  part="I">Tweedledee</cl>
    </cl>
  </l>
  <l>
    <cl  part="F">
      <cl  part="F">Had spoiled his nice new rattle.</cl>
    </cl>
  </l>
</div>
<div  type="stanza">
  <l>
    <cl  part="I">Just then flew down a monstrous crow,</cl>
  </l>
  <l>
    <cl  part="F">As black as a tar barrel;</cl>
  </l>
  <l>
    <cl  part="I">Which frightened both the heroes so,</cl>
  </l>
  <l>
    <cl  part="F">
      <cl>They quite forgot their quarrel.</cl>
    </cl>
```

```
  </l>
</div>
```

Another approach is to use the *next* and *prev* attributes defined in the additional module for linking (chapter *17. Linking, Segmentation, and Alignment*):

```
<l>
  <cl  next="#c5"  xml:id="c3"  part="I">For Tweedledum said
  <cl  next="#c6"  xml:id="c4"  part="I">Tweedledee</cl>
  </cl>
</l>
<l>
  <cl  prev="#c3"  xml:id="c5"  part="F">
    <cl  prev="#c4"  xml:id="c6"  part="F">Had spoiled his nice new rattle.</cl>
  </cl>
</l>
```

Other methods are also possible; for discussion, see chapter *21. Non-hierarchical Structures*.

The *type* attribute on linguistic segment categories can be used to provide additional interpretative information about the category. The *function* attribute on the <cl> and <phr> elements can be used to provide additional information about the function of the category. Legal values for these two attributes are not defined by these Guidelines, but should be documented in the <segmentation> element of the <encodingDesc> element within the document's header. A general approach to the encoding of linguistic categories for parts of a text is discussed in section *18.4. Linguistic Annotation* below.

Using traditional terminology, these attributes provide a convenient way of specifying, for example, that the clause *from whence it came* is a relative clause modifying another, or that the phrase *by the U.S. Supreme Court* is a prepositional post-modifier:

```
<cl>It mattered not
<cl  type="relative"
   function="clause_modifier">from whence it came;</cl>
</cl>
```

```
<phr  type="NP">the year segregation</phr>
<phr>was outlawed</phr>
<phr  type="PP"
  function="postmodifier-agent">by the U.S. Supreme Court.</phr>
```

Segmentation into clauses and phrases can, of course, be combined. Such detailed encodings as the following may require careful formatting if they are to be easily readable however.

```
<p>
  <s>
    <cl  type="finite-declarative"
      function="independent">
      <phr  type="NP"  function="subject">Nineteen fifty-four,
      <cl  type="finite-relative-declarative"
         function="appositive">when <phr  type="NP"  function="subject">I</phr>
         <phr  type="VP"  function="predicate">was eighteen years old</phr>
       </cl>
```

```
    </phr>,
  <phr  type="VP"  function="predicate">
     <phr  type="V"  function="verb-main">is held</phr>
     <phr  type="NP"  function="complement">
      <cl  type="nonfinite"
       function="predicate-nom.">
       <phr  type="V"  function="copula">to be</phr>
       <phr  type="NP"
        function="predicate-nom.">a crucial turning point
       <phr  type="PP"
          function="postmodifier">in
        <phr  type="NP"  function="prep.obj.">the history
          <phr  type="PP"
             function="postmodifier">of the Afro-American</phr>
          </phr>
        </phr>
                 —
       <phr  type="PP"
          function="postmodifier-appositive">for
        <phr  type="NP"  function="prep.obj.">the U.S.A.
          <phr  type="PP"
             function="postmodifier">as a whole</phr>
          </phr>
        </phr>
       </phr>
              —
      <phr  type="NP"
         function="appositive-predicate-nom.">the year
        <cl  type="finite-relative"
           function="adjectival">
           <phr  type="NP"  function="subject">segregation</phr>
           <phr  type="VP"  function="predicate">
            <phr  type="V"  function="verb-main">was outlawed</phr>
            <phr  type="PP"
              function="postmodifier">by the U.S. Supreme Court</phr>
           </phr>
          </cl>
        </phr>
       </cl>
     </phr>
   </phr>.</cl>
</s>
<s>
  <cl  type="finite-declarative"
    function="independent">
    <phr  type="NP"  function="subject">It</phr>
    <phr  type="VP"  function="predicate">
      <phr  type="V"  function="verb-main">was</phr>
          also
    <phr  type="NP"
       function="predicate-nom.">a crucial year for me</phr>
    </phr>
    <cl  type="declarative-finite"
      function="dependent-causative">because
    <phr  type="PP"
       function="sentence_adverb">on June 18, 1954</phr>,
    <phr  type="NP"  function="subject">I</phr>
```

```
      <phr type="VP" function="predicate">
        <phr type="V" function="verb-main">began serving</phr>
        <phr type="NP" function="complement">a sentence in state prison
        <phr type="PP" function="complement">for possession of marijuana</phr>
        </phr>
      </phr>
    </cl>
  </cl>
 </s>.
</p>
```

This style of markup may introduce spurious new lines and blanks into the text. If the original layout is important, it should be explicitly encoded, using such facilities as the <lb> element, the global *rend* or *rendition* attributes, etc.

The <w>, <m>, and <c> elements are identical in meaning to the <seg> element with a *type* attribute of 'w', 'm', or 'c' respectively, and may occur wherever <seg> is permitted to occur. However, their content is more constrained than <seg>: for example, the <w> element should only contain <w>, <m>, <c> elements or <pc> elements, or plain text; the <m> element should contain only <c> or <pc> elements or plain text; both the <c> and <pc> elements should contain only plain text, most often only a single character or a sequence of graphemes to be treated as a single character. Consequently, while these more specific elements can be translated directly into typed <seg> elements, the reverse is not necessarily the case.

The restriction on the content of the <w> element in particular requires that a certain care must be exercised when using it, especially in relation to the use of other tags that one may think of as *word level*, but which are in fact defined as *phrase level*. Consider the problem of segmenting an occurrence of the <mentioned> element as a word.

```
<mentioned>grandiloquent</mentioned>
```

The first of the following two encodings is legitimate; the second is not, since the <mentioned> element is not part of the content model of the <w> element:

```
<mentioned>
  <w>grandiloquent</w>
</mentioned>
```

```
<w>
  <mentioned>grandiloquent</mentioned>
</w>
```

On the other hand, both of the following encodings *are* legitimate:

```
<mentioned>
  <phr>grandiloquent speech</phr>
</mentioned>
```

```
<phr>
  <mentioned>grandiloquent speech</mentioned>
</phr>
```

The first encoding describes the citing of a phrase. The second describes a phrase which consists of something mentioned.

The <w> element carries additional attributes which may be of use in many indexing or analytic applications. The *lemma* attribute may be used to specify the *lemma*, that is the head- or uninflected form of an inflected verb or noun, for example:

```
<s xml:lang="la">
  <w lemma="timeo">timeo</w>
  <w lemma="danaii">Danaos</w>
  <w lemma="et">et</w>
  <w lemma="donum">dona</w>
  <w lemma="fero">ferentes</w>
</s>
```

In some situations it may be more convenient to use the *lemmaRef* pointer attribute than to supply an explicit uninflected form. This attribute assumes the existence of a list of uninflected forms, for example in an online lexicon, with which individual w entries can be associated using the usual TEI pointer mechanisms. Assuming that a standardized lexicon for Latin is available at the location `http://lexicon.org/latin.xml`, we might for example revise the above example as:

```
<s xml:lang="la">
  <w lemmaRef="http://lexicon.org/latin.xml#timeo">timeo</w>
  <w lemmaRef="http://lexicon.org/latin.xml#danaii">Danaos</w>
<!-- ... -->
</s>
```

18.1.2 Below the Word Level

It is sometimes helpful to markup explicitly sub-word components such as morphemes, characters, or punctuation.

`<m>` (morpheme) represents a grammatical morpheme.

`<c>` (character) represents a character.

`<pc>` (punctuation character) contains a character or string of characters regarded as constituting a single punctuation mark.

The <m> element is used to mark up morphologically identified segmentation below the word level. Analogous to the *lemma* attribute for <w>, there is a *baseForm* attribute for the <m> element, which may be used to indicate the 'base form' of an inflected morpheme; where appropriate, <m> elements may also be organized hierarchically:

```
<w type="adjective">
  <m type="base">
    <m type="prefix" baseForm="con">com</m>
    <m type="root">fort</m>
  </m>
  <m type="suffix">able</m>
</w>
```

The distinction between <m> and <w> is provided as a convenience only; it may not be appropriate for all linguistic theories, nor is it meaningful in all languages. The intention is to provide a means for those cases where it is considered helpful to distinguish lexical from sub-lexical tokens, to complement the more general mechanism already provided by the <seg> element, using which the above example could alternatively be marked up as follows:

```
<seg type="adjective">
  <seg type="base">
    <seg type="prefix">com</seg>
    <seg type="morph">fort</seg>
  </seg>
  <seg type="suffix">able</seg>
</seg>
```

See section *18.4.2. Lightweight Linguistic Annotation* for an alternative to using *type* in such contexts.

There is a substantial linguistic difference between characters like letters or diacritics and punctuation marks. The former are used to construct meaningful units like morphemes or words. The latter are functionally independent units acting at the level of syntactic units. A word may consist of a single letter (for example 'I' in English), but this does not mean that we should use <c> instead of <w> to mark it up.

The <c> (character) element should be used to mark up any non-lexical character, whether this appears within a word, or outside it. In the following example, the encoder wishes to indicate that the letters are not to be regarded as words:

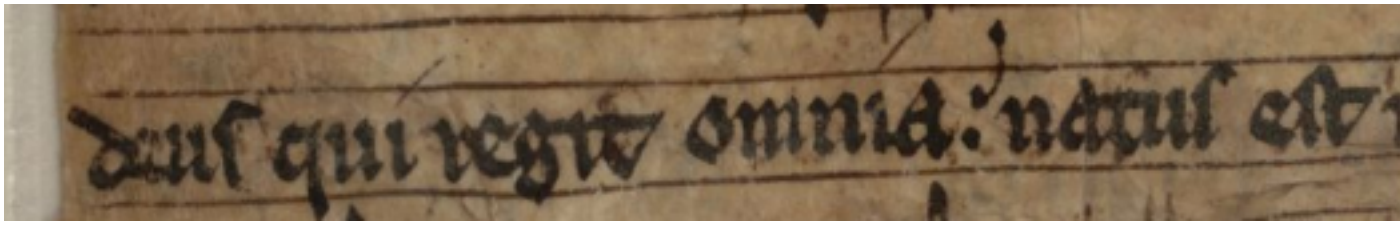
```
<phr>
  <c>M</c>
  <c>O</c>
  <c>A</c>
  <c>I</c>
  <w>doth</w>
  <w>sway</w>
  <w>my</w>
  <w>life</w>
</phr>
```

The <c> element may be used for individual characters occurring within a <w> or <m> element which it is desired to distinguish for some reason, as in the following examples:

```
<m baseForm="not">
  <c>n</c>
  <c type="punct">'</c>
  <c>t</c>
</m>
```

This encoding represents the constituents of a common abbreviation, but does not indicate that it is in fact an abbreviation; the <am> element (*12.3.1.2. Abbreviation and Expansion*) may be preferred for the latter purpose. Generally speaking, the use of <c> use to mark non-lexical punctuation marks is deprecated, since the <pc> element is provided specifically to distinguish these.

The <pc> (punctuation character) element should be used to mark up characters which are specifically regarded as providing punctuation, rather than constituting parts of a word. It may be particularly useful when transcribing older written materials, in which an encoding of the original punctuation may be useful for interpretive or analytic purposes, in much the same way as an encoding of the original orthography may be. For example, in the following extract from a Bodleian Library musical manuscript two different punctuation marks are used to distinguish kinds of pause in the text. The *punctus elevatus* (which resembles an inverted semicolon) is not a Unicode character, but may still be encoded using the <g> element. As further described in chapter *5. Characters, Glyphs, and Writing Modes*, this element points to a definition for the intended character which may be stored either locally or elsewhere.



```
deus qui regis omnia
<pc>
  <g  ref="#pelev">;</g>
</pc> natus est in bethlehem
<pc>.</pc>o <pc>.</pc> mira gratia...

<!-- elsewhere -->
<char  xml:id="pelev">
<!-- definition of the punctus elevatus character -->
</char>
```

The <pc> element carries special attributes to record analyses of the functional behaviour or classification of the punctuation mark it contains. The *unit* attribute may be used, as on the <milestone> element to name the kind of unit which the punctuation mark delimits, for example a paragraph or section. The *pre* attribute may be used to indicate whether the punctuation precedes or follows the unit it delimits. The *force* attribute indicates the strength of the association between the punctuation mark and its adjacent word.

In the following example, the paragraph marker (¶) has been tagged as a strong punctuation mark, preceding the unit it marks, which is named 'para':

```
<p>
  <pc  unit="para"  force="strong"  pre="true">¶</pc>Incipit...
</p>
```

A similar encoding can be used for hyphenation:

```
A fire<pc  force="strong">-</pc>proof vest is recom<pc  force="weak">-</pc><lb/>
mended.
```

Refer to *3.2.2. Hyphenation* for a discussion of the motivations for explicitely recording the presence of hyphens.

The <w>, <m>, <c>, and <pc> elements can be used together to give a fairly detailed low-level grammatical analysis of text. For example, consider the following segmentation of the English S-unit *I didn't do it.*

```
<w>I</w>
<w>
  <m  baseForm="do">did</m>
  <m>n't</m>
</w>
<w  lemma="do">do</w>
<w>it</w>
<pc>.</pc>
```

This segmentation, crude as it is, succeeds in representing the idea that *did* occurring as a morphological component of the word *didn't* has something in common with the word <do>. A further advantage of segmenting

the text down to this level is that it becomes relatively simple to associate each such segment with a more detailed formal analysis, for example by providing a baseform, or morphological analysis at whichever level is appropriate. This matter is taken up in detail in section *18.4. Linguistic Annotation*.

18.2 Global Attributes for Simple Analyses

When the module described by this chapter is selected, an additional attribute is defined for all elements:

`att.global.analytic` provides additional global attributes for associating specific analyses or interpretations with appropriate portions of a text.

- `@ana` (analysis) indicates one or more elements containing interpretations of the element on which the *ana* attribute appears.

The *ana* attribute may be specified for any element. Its effect is to associate the element with one or more others representing an analysis or interpretation of it. Its target should be one of the elements described in the section *18.3. Spans and Interpretations* below, or some other interpretative element such as <note>, on which see section *3.9. Notes, Annotation, and Indexing* or <fs>, on which see chapter *19. Feature Structures*. If a hierarchical form of classification is desired then it may point to <category> element at a suitable level in a <taxonomy> see *2.3.7. The Classification Declaration*.

18.3 Spans and Interpretations

The simplest mechanisms for attaching analytic notes in some structured vocabulary to particular passages of text are provided by the and <interp> elements, and their associated grouping elements <spanGrp> and <interpGrp>.

`<span>` associates an interpretative annotation directly with a span of text.

`<spanGrp>` (span group) collects together span tags.

`<interp>` (interpretation) summarizes a specific interpretative annotation which can be linked to a span of text.

`<interpGrp>` (interpretation group) collects together a set of related interpretations which share responsibility or type.

These elements are all members of the class `att.interpLike`, and thus share the following attribute:

`att.interpLike` provides attributes for elements which represent a formal analysis or interpretation.

- `@inst` (instances) points to instances of the analysis or interpretation represented by the current element.

They also inherit the following attributes from `att.global.responsibility`:

`att.global.responsibility` provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

- `@cert` (certainty) signifies the degree of certainty associated with the intervention or interpretation.
- `@resp` (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

The *type* attribute of the and <interp> elements may be used to indicate that the annotations are of specific types, for example thematic or structural. The annotation itself is supplied as the content of the or <interp> element. In the case of the element, the span of text being annotated is indicated by values of the *from*, *to* or *target* attributes, used in combination as follows. If only the *from* attribute is supplied, then the span is coterminous with the element indicated by its value; if both *from* and *to* are supplied, the span runs from the start of the element indicated by the *from* attribute up to the end of the element indicated by the *to* attribute; if the *target* attribute is used, the span is defined by aggregating the contents of the (possibly non-contiguous) elements pointed to by its values. It is an error to supply only the *to* attribute; to supply more than one pointer value for either *to* or *from* attributes; or to supply either of these in conjunction with the *target* attribute. In the case of <interp> (see below), the span is indicated by a pointer from a <link> element or some similar mechanism. The *resp* attribute indicates the annotator responsible for this annotation.

The element provides a simple way of indicating such features as phrasal verbs in a linguistic analysis, as in this example:

```
<s>
  <w>What</w>
  <w>did</w>
  <w>you</w>
  <w  xml:id="mk01">make</w>
  <w  xml:id="up01">up</w>
</s>
<span  from="#mk01"  to="#up01">phrasal verb "make up"</span>
```

Here the two components of the span follow each other, so the *to* and *from* attributes may be used. The same effect could however be achieved by using the *target* attribute:

```
<s>
  <w>What</w>
  <w>did</w>
  <w>you</w>
  <w  xml:id="mk02">make</w>
  <w  xml:id="up02">up</w>
</s>
<span  target="#mk02 #up02">phrasal verb "make up"</span>
```

This second approach might be cumbersome if the number of components to be combined is very large. It is however essential if the components do not follow each other, as in this example:

```
<s>
  <w>Did</w>
  <w>you</w>
  <w  xml:id="mk03">make</w>
  <w>it</w>
  <w  xml:id="up03">up</w>
</s>
<span  target="#mk03 #up03">phrasal verb "make up"</span>
```

The element can be used for any kind of annotation. In this example it is used in a narratological analysis:

```
<p  xml:id="MaQp1s2p114">
  <s  xml:id="MaQp1s2p114s1">There was certainly a definite point at which the
     thing began.</s>
  <s  xml:id="MaQp1s2p114s2">It was not; then it was suddenly inescapable,
     and nothing could have frightened it away.</s>
  <s  xml:id="MaQp1s2p114s3">There was a slow integration, during which she,
     and the little animals, and the moving grasses, and the sun-warmed
     trees, and the slopes of shivering silvery mealies, and the great
     dome of blue light overhead, and the stones of earth under her feet,
     became one, shuddering together in a dissolution of dancing
     atoms.</s>
  <s  xml:id="MaQp1s2p114s4">She felt the rivers under the ground forcing
     themselves painfully along her veins, swelling them out in an
     unbearable pressure; her flesh was the earth, and suffered growth
     like a ferment; and her eyes stared, fixed like the eye of the
     sun.</s>
  <s  xml:id="MaQp1s2p114s5">Not for one second longer (if the terms for time
     apply) could she have borne it; but then, with a sudden movement
```

```
    forwards and out, the whole process stopped; and <emph  rend="italic">that</emph>
was <soCalled  rend="dquo">the
       moment</soCalled> which it was impossible to remember
    afterwards.</s>
  <span  from="#MaQp1s2p114s3"
    to="#MaQp1s2p114s5">the moment</span>
  <s  xml:id="MaQp1s2p114s6">For during that space of time (which was
    timeless) she understood quite finally her smallness, the
    unimportance of humanity.</s>
</p>
```

The element may, as in this example, be placed in the text near the textual span it is associated with. Alternatively, it may be placed elsewhere in the same or a different document. Where several or <interp> elements share the same attributes, for example having the same responsibility or type, it may be convenient to group them within a <spanGrp> or <interpGrp> element as follows:

```
<spanGrp  resp="#DTL">
  <span  from="#MaQp1s2p114s3"
    to="#MaQp1s2p114s5">the moment</span>
<!-- other spans identified by DTL here -->
</spanGrp>
```

Spans may also be used to represent structural divisions within a narrative, particularly when these do not coincide with the structure implied by the element structure. Consider the following narrative:

> Sigmund, the son of Volsung, was a king in Frankish country. Sinfiotli was the eldest of his sons, the second was Helgi, the third Hamund. Borghild, Sigmund's wife, had a brother named — But Sinfiotli, her stepson, and — both wooed the same woman and Sinfiotli killed him over it.[112] And when he came home, Borghild asked him to go away, but Sigmund offered her weregild, and she was obliged to accept it. At the funeral feast Borghild was serving beer. She took poison, a big drinking horn full, and brought it to Sinfiotli. When Sinfiotli looked into the horn, he saw that poison was in it, and said to Sigmund 'This drink is cloudy, old man.' Sigmund took the horn and drank it off. It is said that Sigmund was hardy and that poison did him no harm, inside or out. And all his sons could tolerate poison on their skin. Borghild brought another horn to Sinfiotli, and asked him to drink, and everything happened as before. And a third time she brought him a horn, and reproachful words as well, if he didn't drink from it. He spoke again to Sigmund as before. He said 'Filter it through your mustache, son!' Sinfiotli drank it off and at once fell dead.
>
> Sigmund carried him a long way in his arms and came to a long, narrow fjord, and there was a small boat there and a man in it. He offered to ferry Sigmund over the fjord. But when Sigmund carried the body out to the boat, it was fully laden. The man said Sigmund should go around the fjord inland. The man pushed the boat out and then suddenly vanished.
>
> King Sigmund lived a long time in Denmark in the kingdom of Borghild, after he married her. Then he went south to Frankish lands, to the kingdom he had there. Then he married Hiordis, the daughter of King Eylimi. Their son was Sigurd. King Sigmund fell in a battle with the sons of Hunding. And then Hiordis married Alf, the son of King Hialprec. Sigurd grew up there as a boy.
>
> Sigmund and all his sons were tall and outstanding in their strength, their growth, their intelligence, and their accomplishments. But Sigurd was the most outstanding of all, and everyone who knows about the old days says he was the most outstanding of men and the noblest of all the warrior kings.

A structural analysis of this text, dividing it into narrative units in a pattern shared with other texts from the same literature, might look like this:

[112] The rule marks spaces left for the missing name in the manuscript.

```
<p xml:id="P1">
  <s xml:id="S1">Sigmund ... was a king in Frankish country.</s>
  <s xml:id="S2">Sinfiotli was the eldest of his sons.</s>
  <s xml:id="S3">Borghild, Sigmund's wife, had a brother ...</s>
  <s xml:id="S4A">But Sinfiotli ... wooed the same woman</s>
  <s xml:id="S4B">and Sinfiotli killed him over it.</s>
  <s xml:id="S5">And when he came home, ... she was obliged to accept it.</s>
  <s xml:id="S6">At the funeral feast Borghild was serving beer.</s>
  <s xml:id="S7">She took poison ... and brought it to Sinfiotli.</s>
  <s xml:id="S17">Sinfiotli drank it off and at once fell dead.</s>
  <anchor xml:id="EOS17"/>
</p>
<p xml:id="P2">Sigmund carried him a long way in his arms ... </p>
<p xml:id="P3">King Sigmund lived a long time in Denmark ... </p>
<p xml:id="P4">Sigmund and all his sons were tall ... </p>
<spanGrp resp="#TMA"
  type="narrative-structure">
  <span from="#S1" to="#S3">introduction</span>
  <span from="#S4A">conflict</span>
  <span from="#S4B">climax</span>
  <span from="#S5" to="#S17">revenge</span>
  <span from="#EOS17">reconciliation</span>
  <span from="#P2" to="#P4">aftermath</span>
</spanGrp>
```

Note the use of an empty <anchor> element to provide a target for the 'reconciliation' unit which is normally part of the narrative pattern but which is not realized in the text shown.

The same analysis may be expressed with the <interp> element instead of the element; this element provides attributes for recording an interpretive category and its value, as well as the identity of the interpreter, but does not itself indicate which passage of text is being interpreted; the same interpretive structures can thus be associated with many passages of the text. The association between text passages and <interp> elements should be made either by pointing from the text to the <interp> element with the *ana* attribute defined in section *18.2. Global Attributes for Simple Analyses*, or by pointing at both text and interpretation from a <link> element, as described in chapter *17. Linking, Segmentation, and Alignment*.

To encode the first example above using <interp>, it is necessary to create a text element which contains—or corresponds to—the third, fourth, and fifth orthographic sentences (S-units) in the paragraph. This can be done either with the <seg> element, described in *17.3. Blocks, Segments, and Anchors*, or the <join> element, described in *17.7. Aggregation*. The resulting element can then be associated with the <interp> element using the *ana* attribute described in section *18.2. Global Attributes for Simple Analyses*. We illustrate using the <seg> element.

```
<p xml:id="MarQp1s2p114">
  <s xml:id="MarQp1s2p114s1">There was certainly a definite point ... </s>
  <s xml:id="MarQp1s2p114s2">It was not; then it was suddenly inescapable ... </s>
  <seg xml:id="MarQp1s2p114s3-5"
    ana="#moment">
    <s xml:id="MarQp1s2p114s3">There was a slow integration ... </s>
    <s xml:id="MarQp1s2p114s4">She felt the rivers under the ground ... </s>
    <s xml:id="MarQp1s2p114s5">Not for one second longer ... </s>
  </seg>
  <s xml:id="MarQp1s2p114s6">For during that space of time ... </s>
</p>
<interp xml:id="moment">the moment</interp>
```

The second example above can be recoded using <interp> and <interpGrp> tags in a similar manner. The

interpretation itself can be expressed in an <interpGrp> element, which would replace the <spanGrp> in the example shown above:

```
<interpGrp  resp="#TMA"
  type="structuralunit">
  <interp  xml:id="INTRO">introduction</interp>
  <interp  xml:id="CONFLICT">conflict</interp>
  <interp  xml:id="CLIMAX">climax</interp>
  <interp  xml:id="REVENGE">revenge</interp>
  <interp  xml:id="RECONCIL">reconciliation</interp>
  <interp  xml:id="AFTERM">aftermath</interp>
</interpGrp>
```

Any of these <interp> elements may be linked to the text either by means of the *ana* attribute, or by means of <link> elements. Using the *ana* attribute (on <seg> elements introduced specifically for this purpose), the text would be encoded as follows:

```
<p  xml:id="PP1">
  <seg  xml:id="SS1-SS3"  ana="#INTRO">
    <s  xml:id="SS1">Sigmund ... was a king in Frankish country.</s>
    <s  xml:id="SS2">Sinfiotli was the eldest of his sons.</s>
    <s  xml:id="SS3">Borghild, Sigmund's wife, had a brother ... </s>
  </seg>
  <s  xml:id="SS4A"  ana="#CONFLICT">But Sinfiotli ... wooed the same woman</s>
  <s  xml:id="SS4B"  ana="#CLIMAX">and Sinfiotli killed him over it.</s>
  <seg  xml:id="SS5-SS17"  ana="#REVENGE">
    <s  xml:id="SS5">And when he came home, ... she was obliged to accept it.</s>
    <s  xml:id="SS6">At the funeral feast Borghild was serving beer.</s>
    <s  xml:id="SS17">Sinfiotli drank it off and at once fell dead.</s>
  </seg>
</p>
<anchor  xml:id="NIL1"  ana="#RECONCIL"/>
<p  xml:id="PP2">Sigmund carried him a long way in his arms ... </p>
<p  xml:id="PP3">King Sigmund lived a long time in Denmark ... </p>
<p  xml:id="PP4">Sigmund and all his sons were tall ... </p>
<join  xml:id="PP2-PP4"
  target="#PP2 #PP3 #PP4"  ana="#AFTERM"/>
```

The linkage may also be accomplished using a <linkGrp> element, whose content is a set of <link> elements which point to each interpretive element and its corresponding text unit. This method does not require the use of the *ana* attribute on the text units.

```
<linkGrp  targFunc="interpretation text">
  <link  target="#INTRO #SS1-SS3"/>
  <link  target="#CONFLICT #SS4A"/>
  <link  target="#CLIMAX #SS4B"/>
  <link  target="#REVENGE #SS5-SS17"/>
  <link  target="#RECONCIL #NIL1"/>
  <link  target="#AFTERM #PP2-PP4"/>
</linkGrp>
```

One obvious advantage of using <interp> rather than elements for the Sigmund text is that the <interp> elements can be reused for marking up other texts in the same document, whereas the elements cannot. On the other hand, the use of <interp> elements may require the creation of special text elements not otherwise needed (e.g. the <seg> and the <join> in the revised encoding of the text), whereas the use of elements does not.

18.4 Linguistic Annotation

By *linguistic annotation* we mean here any annotation determined by an analysis of linguistic features of the text, excluding as borderline cases both the formal structural properties of the text (e.g. its division into chapters or paragraphs) and descriptive information about its context (the circumstances of its production, its genre or medium). The structural properties of any TEI-conformant text should be represented using the structural elements discussed elsewhere in this chapter and in chapters *3. Elements Available in All TEI Documents*, *4. Default Text Structure*, *6. Verse*, *7. Performance Texts*, *8. Transcriptions of Speech*, *10. Dictionaries*, and *16. Language Corpora.* The contextual properties of a TEI text are fully documented in the TEI header, which is discussed in chapter *2. The TEI Header*, and in section *16.2. Contextual Information.*

Other forms of linguistic annotation may be applied at a number of levels in a text. A code (such as a word-class or part-of-speech code) may be associated with each word or token, or with groups of such tokens, which may be continuous, discontinuous, or nested. A code may also be associated with relationships (such as cohesion) perceived as existing between distinct parts of a text. The codes themselves may stand for discrete and non-decomposable categories, or they may represent highly articulated bundles of textual features. Their function may be to place the annotated part of the text somewhere within a narrowly linguistic or discoursal domain of analysis, or within a more general semantic field, or any combination drawn from these and other domains.

The manner by which such annotations are generated and attached to the text may be entirely automatic, entirely manual or a mixture. The ease and accuracy with which analysis may be automated may vary with the level at which the annotation is attached. The method employed should be documented in the <interpretation> element within the encoding description of the TEI header, as described in section *2.3.3. The Editorial Practices Declaration.* Where different parts of a language corpus have used different annotation methods, the *decls* attribute may be used to indicate the fact, as further discussed in section *16.3. Associating Contextual Information with a Text.*

18.4.1 Linguistic Annotation by Means of Generic TEI Devices

As one example of such types of analysis, consider the following sentence, taken from the Lancaster/IBM Treebank Project (**?**).

> The victim's friends told police that Kruger drove into the quarry and never surfaced.

Our discussion focuses on the way that this sentence might be analysed using the CLAWS system developed at the University of Lancaster but exactly the same principles may be applied to a wide variety of other systems.[113] Output from the system consists of a segmented and tokenized version of the text, in which word class codes have been associated with each token. CLAWS offers outputs in a variety of non-XML and XML formats: for example, the simplest format for the sample sentence would be:

```
  The_ AT0 victim_ NN1 's_ POS friends_ NN2 told_ VVD police_ NN2 that_ CJT Kruger_
NP0
drove_ VVD into_ PRP the_ AT0 quarry_ NN1 and_ CJC never_ AV0 surfaced_ VVD
```

This may be easily transformed into an equivalent TEI XML representation:

```
<s>
  <w  ana="#AT0">The </w>
  <w  ana="#NN1">victim</w>
  <w  ana="#POS">'s</w>
  <w  ana="#NN2">friends </w>
  <w  ana="#VVD">told </w>
  <w  ana="#NN2">police </w>
  <w  ana="#CJT">that </w>
  <w  ana="#NP0">Kruger </w>
```

[113] For the word-class tagging method used by CLAWS see **?**; For an overview of the system see **?**. The example sentence was processed using an online version of the CLAWS tagger at `http://ucrel.lancs.ac.uk/claws/`

```
  <w  ana="#VVD">drove </w>
  <w  ana="#PRP">into </w>
  <w  ana="#AT0">the </w>
  <w  ana="#NN1">quarry </w>
  <w  ana="#CJC">and </w>
  <w  ana="#AV0">never </w>
  <w  ana="#VVD">surfaced</w>
</s>
```

Although the names used for the attribute values here may have some significance for the human reader (AT0 for *article*, NN1 for *singular noun*, NN2 for *plural noun*, etc.) they are arbitrary codes, used in this case as pointers to other elements which define their significance more precisely. If the codes are considered to be *atomic*, then the <interp> element described in section *18.3. Spans and Interpretations* might be used to supply brief definitions in the header:

```
<interpGrp  type="POS">
  <interp  xml:id="AT0">Definite article</interp>
  <interp  xml:id="AV0">Adverb</interp>
  <interp  xml:id="CJC">Conjunction</interp>
  <interp  xml:id="CJT">Relative that</interp>
  <interp  xml:id="NN1">Noun singular</interp>
  <interp  xml:id="NN2">Noun plural</interp>
  <interp  xml:id="NP0">Proper noun</interp>
  <interp  xml:id="POS">Genitive marker</interp>
  <interp  xml:id="PRP">Preposition</interp>
  <interp  xml:id="VVD">Verb past tense</interp>
</interpGrp>
```

If the codes are considered to be compositional (for example that NN1 and NN2 have something in common, namely their *noun-ness*, which they do not share with, say, VVD), then this compositionality may be most clearly expressed using a mechanism based on the <fs> element defined in chapter *19. Feature Structures*.

This approach requires the text to be fully segmented, using the linguistic segment elements described in section *18.1. Linguistic Segment Categories*, so that the scope of the *ana* attribute used to point to each interpretation is clearly defined. A further analysis into phrase and clause elements can be superimposed on the word and morpheme tagging in the preceding illustration. For example, CLAWS provides the following constituent analysis of the sample sentence (the word class codes have been deleted):

```
  [N [G The victim's G] friends N] [V told [N police N] [Fn that
[N Krueger N] [V [V& drove [P into [N the quarry N]P]V&] and
[V+ never surfaced V+]V]Fn]V]
```

Treating the labels on the brackets as phrase or clause interpretations, this analysis of the structure of the example sentence can be combined with the word class analysis and represented as follows (the symbol V&”/> representing the first part of a coordinate phrase, has been replaced by V1, and V+, representing the second part, has been replaced by V2).

```
<s  type="sentence">
  <phr  ana="#n">
    <phr  ana="#gn">
      <w  ana="#AT0">The</w>
```

```
      <w  ana="#NN1">victim</w>
      <m  ana="#POS">'s</m>
    </phr>
    <w  ana="#NN2">friends</w>
  </phr>
  <phr  ana="#v">
    <w  ana="#VVD">told</w>
    <phr  ana="#n">
      <w  ana="#NN2">police</w>
    </phr>
    <cl  ana="#fn">
      <w  ana="#CJT">that</w>
      <phr  ana="#n">
        <w  ana="#NP0">Krueger</w>
      </phr>
      <phr  ana="#v">
        <phr  ana="#v1">
          <w  ana="#VVD">drove</w>
          <phr  ana="#pr">
            <w  ana="#PRP">into</w>
            <phr  ana="#n">
              <w  ana="#AT0">the</w>
              <w  ana="#NN1">quarry</w>
            </phr>
          </phr>
        </phr>
        <w  ana="#CJC">and</w>
        <phr  ana="#v2">
          <w  ana="#AV0">never</w>
          <w  ana="#VVD">surfaced</w>
        </phr>
      </phr>
    </cl>
  </phr>
  <c  ana="#pun">.</c>
</s>
```

This approach requires the definition of further <interp> (or <fs>) elements to provide targets for the pointers used to represent the constituent analysis:

```
<interpGrp  type="constituentFunction">
  <interp  xml:id="v2">coordinate continuation</interp>
  <interp  xml:id="v">verbal</interp>
  <interp  xml:id="no">nominal</interp>
  <interp  xml:id="gn">genitive</interp>
  <interp  xml:id="fn">finite clause</interp>
  <interp  xml:id="pr">prepositional</interp>
  <interp  xml:id="v1">coordinate start</interp>
</interpGrp>
```

Alternatively, a 'stand-off' representation for these analyses might be created using the <linkGrp> element. In this case, each linguistic segment to be annotated must be supplied with its own *xml:id* attribute:

```
<s>
  <w xml:id="word-1">The</w>
  <w xml:id="word-2">victim</w>
  <w xml:id="word-3">'s</w>
  <w xml:id="word-4">friends</w>
  <w xml:id="word-5">told</w>
  <w xml:id="word-6">police</w>
  <w xml:id="word-7">that</w>
  <w xml:id="word-8">Kruger</w>
  <w xml:id="word-9">drove</w>
  <w xml:id="word10">into</w>
  <w xml:id="word11">the</w>
  <w xml:id="word12">quarry</w>
  <w xml:id="word13">and</w>
  <w xml:id="word14">never</w>
  <w xml:id="word15">surfaced</w>
</s>
```

Each segment-interpretation pair may now be represented by means of a <link> element inside an appropriate <linkGrp> element:

```
<linkGrp type="POS-annotation">
  <link target="#word-1 #AT0"/>
  <link target="#word-2 #NN1"/>
  <link target="#word-3 #POS"/>
  <link target="#word-4 #NN2"/>
  <link target="#word-5 #VVD"/>
  <link target="#word-6 #NN2"/>
<!--... -->
</linkGrp>
```

Each linguistic segment so far discussed has been well-behaved with respect to the basic document hierarchy, having only a single parent. Moreover, the segmentation has been complete, in that each part of the text is accounted for by some segment at each level of analysis, without discontinuities or overlap. This state of affairs does not of course apply in all types of analysis, and these Guidelines provide a number of mechanisms to support the representation of discontinuities or multiple analyses. A brief overview of these facilities is provided in chapter *21. Non-hierarchical Structures*; also see *17. Linking, Segmentation, and Alignment.* These mechanisms all depend to a greater or lesser degree on the use of pointing elements of various kinds.

18.4.2 Lightweight Linguistic Annotation

While these Guidelines offer a variety of means to add linguistic information to textual units and much of that has been presented above, two kinds of use cases and two groups of users call for a dedicated set of specialized attributes to carry linguistic information. One relevant use case is where basic linguistic information gets added to an existing resource, in which generic attributes such as *type* or *ana* have already been used to encode other categorizations and analyses. The other group of users and use cases involves corpus linguists and resources built from scratch as lightly annotated language corpora. In the latter kind of projects, energy and person-hours are not devoted to careful literary analysis and hand-encoding of the relevant phenomena, but rather to the analysis of the completed resources, and therefore the phase of resource-building must be quick and relatively effortless, requiring minimal structural markup, well-established containers for grammatical information, and a standardized way of filling them in.

The aims defined above can be realized by means of lightweight linguistic annotation using attributes that belong to the `att.linguistic` class:

`att.linguistic` provides a set of attributes concerning linguistic features of tokens, for usage within token-level elements, specifically <w> and <pc> in the analysis module.

`@lemma` provides a lemma (base form) for the word, typically uninflected and serving both as an identifier (e.g. in dictionary contexts, as a headword), and as a basis for potential inflections.

`@pos` (part of speech) indicates the part of speech assigned to a token (i.e. information on whether it is a noun, adjective, or verb), usually according to some official reference vocabulary (e.g. for German: STTS, for English: CLAWS, for Polish: NKJP, etc.).

`@msd` (morphosyntactic description) supplies morphosyntactic information for a token, usually according to some official reference vocabulary (e.g. for German: STTS-large tagset; for a feature description system designed as (pragmatically) universal, see Universal Features).

`@join` when present, provides information on whether the token in question is adjacent to another, and if so, on which side.

The essence of lightweight linguistic annotation is that the basic grammatical information is encapsulated at the word level, together with the orthographic shape of the word. This has clear advantages for automatic processing but, on the other hand, this form of data encapsulation also imposes restrictions on the extent of information that can be encoded, essentially limiting it to a single tokenization and lemmatization schema, a single tagset, and a subset of the possible analyses (out from potentially many guesses at the part-of-speech or morphosyntactic descriptions, single values have to fit into the existing attributes). Another important principle that this kind of annotation is sensitive to is the need for (near) homomorphism between the assumed tokenization (division of the text stream into minimal units) and the division into minimal syntactic units (*word forms*, in the terminology of ISO Morpho-Syntactic Framework, ISO 24611[114]), because it is the former that results from the process of tokenization, but the latter that can be lemmatized and meaningfully described by means of grammatical features. Where tokens are only minimally mismatched with word forms, various repair strategies can be used (e.g., recursing <w> to capture multi-token compounds or using `att.fragmentable` to point at disjoint tokens). Beyond that, more robust TEI mechanisms, based on standoff principles and feature structures, should replace lightweight annotation.

The basic grammatical information encoded by means of `att.linguistic` is sufficient for the purpose of enhancing queries or improving the analysis of search results by, for example, making it possible to distinguish between the noun *cut* and the identically spelled verb *cut* in English, and further between e.g. the present-tense form of *cut* and its past-tense or past-participial forms. For the former contrast, the part-of-speech (*pos*) attribute should be used, whereas the latter may use *pos* and/or *msd* attributes, depending on the annotation vocabulary adopted for the project in question. The various grammatical realizations of a single 'dictionary word' can be captured by means of the attribute *lemma*, which provides a common label for them. For example, English verbs are typically lemmatized as the base form (also called *bare infinitive*), so the value of *lemma* for the verbal forms *write*, *writes*, *wrote*, *written*, and *writing* is typically write.

Together with the span-delimiting elements mentioned in this section, such as <s>, <cl>, or <phr>, lightweight grammatical annotation may be used to build basic syntactic constituency structures, where hierarchical information is expressed through span containment rather than by relations among tree nodes. This is however the limit of this kind of annotation: for the purpose of describing true constituency or dependency syntactic structures, one needs to turn to more robust mechanisms offered by the TEI, which may involve graph description (see chapter *20. Graphs, Networks, and Trees*) or standoff techniques (see section *17.9. Stand-off Markup*), and where grammatical labels may need to be annotated by means of feature structures (see chapter *19. Feature Structures*).

Some of the above-mentioned robust methods will also prove handy in cases where more than one tagset (label inventory) is used to label the words, or where automatic morphological analysis yields multiple possibilities (for example, the form *cutting* is morphologically ambiguous between verbal, adjectival, and nominal) and needs to be followed by (often also automatic) disambiguation in morphosyntactic contexts, with varying probabilities that may also need to be recorded together with their corresponding part-of-speech and morphosyntactic values.

It should be borne in mind that tokenization, lemmatization, part-of-speech identification, and morphosyntactic labelling, especially when performed automatically, should in most cases be seen as involving pragmatic decisions, dictated by concrete practical goals, economy of description, or the demands of particular analytic and/or visualization tools. It comes therefore as no surprise that numerous alternative (and often conflicting) lemmatization strategies and tagsets exist, in use by various communities and various tools, and that they change with time (a case in point is the CLAWS tagset for English, with several versions that merge the part-of-speech and morphosyntactic

[114] All definitions contained within ISO standards can be accessed at the ISO Online Browsing Platform. For ISO MAF, see `https://www.iso.org/obp/ui#iso:std:iso:24611:ed-1:v1:en`.

information to various degrees). [115] The nature and description of these systems is outside the scope of these Guidelines, but it has to be stressed that all the strategies adopted for linguistic annotation, even at the lightweight level of complexity, *must* be documented in the header of the given electronic resource, not only for the purpose of guaranteeing successful data interpretation and exchange, but also for the sake of sustainability of the results of the given project.

The last of the att.linguistic attributes, *join*, has the most text-technological flavour. It can be used to amend the loss of whitespace-related information in non-inline markup.

Compare the following two listings. The first difference between them is in the tagset used (CLAWS-5 vs. CLAWS-7) and only serves to exemplify the need to document the choice of descriptive vocabulary in the header, lest the encoded information is unreadable or confusing. The second difference is the difference in the treatment of inter-token whitespace, and it is here that the *join* attribute proves indispensable.

The first example listing uses CLAWS-5 and inline annotation, where whitespace serves as part of the markup:

```
<s><w pos="AT0">The</w> <w pos="NN1">victim</w><w pos="POS">'s</w> <w pos="NN2">friends</w>
   <w pos="VVD">told</w> <w pos="NN2">police</w> <w pos="CJT">that</w> <w pos="NP0">Kruger</w>
   <w pos="VVD">drove</w> <w pos="PRP">into</w> <w pos="AT0">the</w> <w pos="NN1">quarry</w>
   <w pos="CJC">and</w> <w pos="AV0">never</w> <w pos="SENT">surfaced</w><pc pos="PUN">.</pc></
```

In the second example, the attribute *join* is the only way to encode whether two tokens are adjacent or not:

```
<s>
  <w pos="AT">The</w>
  <w pos="NN1">victim</w>
  <w pos="GE" join="left">'s</w>
  <w pos="NN2">friends</w>
  <w pos="VVD">told</w>
  <w pos="NN2">police</w>
  <w pos="CST">that</w>
  <w pos="NP1">Kruger</w>
  <w pos="VVD">drove</w>
  <w pos="II">into</w>
  <w pos="AT">the</w>
  <w pos="NN1">quarry</w>
  <w pos="CC">and</w>
  <w pos="RR">never</w>
  <w pos="VVD">surfaced</w>
  <pc pos="." join="left">.</pc>
</s>
```

Note that projects will need to decide whether they want to redundantly encode full information on the adjacency of each token (in which case, the above listing should also have *join* with the value right on the tokens *victim* and *surfaced*, or whether information on a single direction of adjacency is enough. Strategies vary, and it is important to document them in the TEI header.

The following example shows a German sentence *Wir fahren in den Urlaub.* ('We're going on vacation.') annotated with all the attributes discussed above.[116]

[115] Given that the English language has relatively poor inflectional morphology, the decision to merge part-of-speech symbols with morphosyntactic features (as in, e.g., CLAWS-7, where the value PPHO1 signals the 3rd person singular objective personal pronoun) is fully justified as the most economical approach. For languages with more robust inflection, the *pos* and *msd* attributes will either be used separately, or the part-of-speech information will be merged into the morphosyntactic description.

[116] The annotation values have been adapted from the CLARIN Weblicht service, where e.g. the full morphosyntactic description of the first item reads: `[cat pronoun, personal true, substituting true, person 1, case nominative, number plural]`, and has been mapped from a sequence of attribute-value pairs suitable for feature structure notation, into a compressed form that fits inside a single attribute value.

```
<s>
  <w pos="PPER" lemma="wir"
    msd="pers:subst:p1:nom:pl">Wir</w>
  <w pos="VVFIN" lemma="fahren"
    msd="p1:pl:pres:ind">fahren</w>
  <w pos="APPR" lemma="in" msd="--">in</w>
  <w pos="ART" lemma="d"
    msd="def:acc:sg:masc">den</w>
  <w pos="NN" lemma="Urlaub"
    msd="acc:sg:masc">Urlaub</w>
  <pc pos="$." lemma="." msd="--" join="left">.</pc>
</s>
```

The final examples lay out a strategy for dealing with e.g. historical corpora where it is on the one hand important to maintain a steady stream of token-level elements (<w> and <pc>) for efficient processing, but, on the other hand, it is also important to either record the original spelling (when the corpus text is normalized) or to record the normalized variants (when the element content of the corpus preserves the original spelling). The attribute class `att.lexicographic.normalized` can be used for that purpose:

`att.lexicographic.normalized` provides attributes for usage within word-level elements in the analysis module and within lexicographic microstructure in the dictionaries module.

- `@norm` (normalized) provides the normalized/standardized form of information present in the source text in a non-normalized form.
- `@orig` (original) gives the original string or is the empty string when the element does not appear in the source text.

The first fragment below comes from "Gottfried, Newe Welt Vnd Americanische Historien. Frankfurt/M., 1631" encoded in the Deutsches Textarchiv and records normalized forms in the *norm* attribute.

```
<w norm="unvermutete">vnuermuthete</w>
<w norm="Freundschaft">Freundſchafft</w>
<w norm="angeboten">angebotten</w>
```

The following example comes from the EarlyPrint project and uses the attribute *orig* to record the original spelling (note that the *xml:id* attributes have been removed for the sake of readability).

```
<w lemma="he" pos="pns">he</w>
<w lemma="have" pos="vvz">hath</w>
<w lemma="bring" pos="vvn">brought</w>
<w lemma="forth" pos="av" orig="sorth">forth</w>
```

18.4.3 Spoken Text

The mechanisms proposed in this chapter may also be used to encode analyses of an entirely different kind, for example discourse function. Here is an application of the span technique to record details of a sales transaction in a spoken text.

```
<u xml:id="u1">Can I have ten oranges and a kilo of bananas please?</u>
<u xml:id="u2">Yes, anything else?</u>
<u xml:id="u3">No thanks.</u>
<u xml:id="u4">That'll be dollar forty.</u>
<u xml:id="u5">Two dollars</u>
<u xml:id="u6">Sixty, eighty, two dollars. Thank you.</u>
```

```
<spanGrp  type="transactions">
  <span  from="#u1">sale request</span>
  <span  from="#u2"  to="#u3">sale compliance</span>
  <span  from="#u4">sale</span>
  <span  from="#u5">purchase</span>
  <span  from="#u6">purchase closure</span>
</spanGrp>
```

For further discussion of the <u> (utterance) element and other elements recommended for transcriptions of spoken language, see chapter *8. Transcriptions of Speech*.

18.5 Module for Analysis and Interpretation

The module described in this chapter makes available the following components:

Module analysis: Simple analytic mechanisms

- *Elements defined*: c cl interp interpGrp m pc phr s span spanGrp w
- *Classes defined*: att.global.analytic att.lexicographic.normalized att.linguistic

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

19 Feature Structures

A *feature structure* is a general purpose data structure which identifies and groups together individual *features*, each of which associates a name with one or more values. Because of the generality of feature structures, they can be used to represent many different kinds of information, but they are of particular usefulness in the representation of linguistic analyses, especially where such analyses are partial, or *underspecified*. Feature structures represent the interrelations among various pieces of information, and their instantiation in markup provides a *metalanguage* for the generic representation of analyses and interpretations. Moreover, this instantiation allows feature values to be of specific *types*, and for restrictions to be placed on the values for particular features, by means of *feature system declarations*.[117]

19.1 Organization of this Chapter

This chapter is organized as follows. Following this introduction, section *19.2. Elementary Feature Structures and the Binary Feature Value* introduces the elements <fs> and <f>, used to represent feature structures and features respectively, together with the elementary *binary* feature value. Section *19.3. Other Atomic Feature Values* introduces elements for representing other kinds of atomic feature values such as *symbolic*, *numeric*, and *string* values. Section *19.4. Feature Libraries and Feature-Value Libraries* introduces the notion of predefined *libraries* or groups of features or feature values along with methods for referencing their components. Section *19.5. Feature Structures as Complex Feature Values* introduces complex values, in particular feature-structures as values, thus enabling feature structures to be recursively defined. Section *19.7. Collections as Complex Feature Values* discusses other complex values, in particular values which are collections, organized as *set*s, *bag*s, and *list*s. Section *19.8. Feature Value Expressions* discusses how the operations of alternation, negation, and collection of feature values may be represented. Section *19.9. Default Values* discusses ways of representing underspecified, default, or uncertain values. Section *19.10. Linking Text and Analysis* discusses how analyses may be linked to other parts of an encoded text. Section *19.11. Feature System Declaration* describes the *feature system declaration*, a construct which provides for the validation of typed feature structures. Formal definitions for all the elements introduced in this chapter are provided in section *19.12. Formal Definition and Implementation*.

19.2 Elementary Feature Structures and the Binary Feature Value

The fundamental elements used to represent a feature structure analysis are <f> (for *feature*), which represents a feature-value pair, and <fs> (for *feature structure*), which represents a structure made up of such feature-value pairs. The <fs> element has an optional *type* attribute which may be used to represent typed feature structures, and may contain any number of <f> elements. An <f> element has a required *name* attribute and an associated *value*. The value may be simple: that is, a single binary, numeric, symbolic (i.e. taken from a restricted set of legal values), or string value, or a collection of such values, organized in various ways, for example, as a list; or it may be complex, that is, it may itself be a feature structure, thus providing a degree of recursion. Values may be under-specified or defaulted in various ways. These possibilities are all described in more detail in this and the following sections.

Feature and feature-value representations (including feature structure representations) may be embedded directly at any point in an XML document, or they may be collected together in special-purpose feature or feature-value *libraries*. The components of such libraries may then be referenced from other feature or feature-value representations, using the *feats* or *fVal* attribute as appropriate.

We begin by considering the simple case of a feature structure which contains binary-valued features only. The following three XML elements are needed to represent such a feature structure:

`<fs>` (feature structure) represents a *feature structure*, that is, a collection of feature-value pairs organized as a structural unit.

`@type` specifies the type of the feature structure.

`@feats` (features) references the feature-value specifications making up this feature structure.

`<f>` (feature) represents a *feature value specification*, that is, the association of a name with a value of any of several different types.

[117] The recommendations of this chapter have been adopted as ISO Standard 24610-1 *Language Resource Management — Feature Structures — Part One: Feature Structure Representation*

`@name` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), providing a name for the feature.

`@fVal` (feature value) references any element which can be used to represent the value of a feature.

`<binary>` (binary value) represents the value part of a feature-value specification which can contain either of exactly two possible values.

The attributes *feats* and the *fVal* are not discussed in this section: they provide an alternative way of indicating the content of an element, as further discussed in section *19.4. Feature Libraries and Feature-Value Libraries*.

An <fs> element containing <f> elements with binary values can be straightforwardly used to encode the *matrices* of feature-value specifications for phonetic segments, such as the following for the English segment [s].

```
  +--- ---+ | consonantal + | | vocalic - | | voiced - | | anterior + | | coronal + |
| continuant + | | strident + | +--- ---+
```

This representation may be encoded in XML as follows:

```
<fs  type="phonological_segments">
  <f  name="consonantal">
    <binary  value="true"/>
  </f>
  <f  name="vocalic">
    <binary  value="false"/>
  </f>
  <f  name="voiced">
    <binary  value="false"/>
  </f>
  <f  name="anterior">
    <binary  value="true"/>
  </f>
  <f  name="coronal">
    <binary  value="true"/>
  </f>
  <f  name="continuant">
    <binary  value="true"/>
  </f>
  <f  name="strident">
    <binary  value="true"/>
  </f>
</fs>
```

Note that <fs> elements may have an optional *type* attribute to indicate the kind of feature structure in question, whereas <f> elements must have a *name* attribute to indicate the name of the feature. Feature structures need not be typed, but features must be named. Similarly, the <fs> element may be empty, but the <f> element must specify its value either directly as content, by means of the *fVal* attribute, or implicitly by reference to a feature system declaration.

The restriction of specific features to specific types of values (e.g. the restriction of the feature *strident* to a binary value) requires additional validation, as does any restriction on the features available within a feature structure of a particular type (e.g. whether a feature structure of type *phonological segment* necessarily contains a feature *voiced*). Such validation may be carried out at the document level, using special purpose processing, at the schema level using additional validation rules, or at the declarative level, using an additional mechanism such as the *feature-system declaration* discussed in *19.11. Feature System Declaration*.

Although we have used the term *binary* for this kind of value, and its representation in XML uses values such as `true` and `false` (or, equivalently, `1` and `0`), it should be noted that such values are not restricted to propositional assertions. As this example shows, this kind of value is intended for use with any binary-valued feature.

19.3 Other Atomic Feature Values

Features may take other kinds of atomic value. In this section, we define elements which may be used to represent: *symbolic values*, *numeric values*, and *string values*. The module defined by this chapter allows for the specification of additional datatypes if necessary, by extending the underlying class `model.featureVal.single`. If this is done, it is recommended that only the basic W3C datatypes should be used; more complex datatyping should be represented as feature structures.

`<symbol>` (symbolic value) represents the value part of a feature-value specification which contains one of a finite list of symbols.

`@value` supplies a symbolic value for the feature, one of a finite list that may be specified in a feature declaration.

`<numeric>` (numeric value) represents the value part of a feature-value specification which contains a numeric value or range.

`<string>` (string value) represents the value part of a feature-value specification which contains a string.

The <symbol> element is used for the value of a feature when that feature can have any of a small, finite set of possible values, representable as character strings. For example, the following might be used to represent the claim that the Latin noun form *mensas* (tables) has accusative case, feminine gender, and plural number:

```
<fs>
  <f  name="case">
    <symbol  value="accusative"/>
  </f>
  <f  name="gender">
    <symbol  value="feminine"/>
  </f>
  <f  name="number">
    <symbol  value="plural"/>
  </f>
</fs>
```

More formally, this representation shows a structure in which three features (*case*, *gender*, and *number*) are used to define morpho-syntactic properties of a word. Each of these features can take one of a small number of values (for example, case can be `nominative`, `genitive`, `dative`, `accusative`, etc.) and it is therefore appropriate to represent the values taken in this instance as <symbol> elements. Note that, instead of using a symbolic value for grammatical number, one could have named the feature *singular* or *plural* and given it an appropriate binary value, as in the following example:

```
<fs>
  <f  name="case">
    <symbol  value="accusative"/>
  </f>
  <f  name="gender">
    <symbol  value="feminine"/>
  </f>
  <f  name="singular">
    <binary  value="false"/>
  </f>
</fs>
```

Whether one uses a binary or symbolic value in situations like this is largely a matter of taste.

The <string> element is used for the value of a feature when that value is a string drawn from a very large or potentially unbounded set of possible strings of characters, so that it would be impractical or impossible to use the <symbol> element. The string value is expressed as the content of the <string> element, rather than as an attribute value. For example, one might encode a street address as follows:

```
<fs>
  <f  name="address">
    <string>3418 East Third Street</string>
  </f>
</fs>
```

The <numeric> element is used when the value of a feature is a numeric value, or a range of such values. For example, one might wish to regard the house number and the street name as different features, using an encoding like the following:

```
<fs>
  <f  name="houseNumber">
    <numeric  value="3418"/>
  </f>
  <f  name="streetName">
    <string>East Third Street</string>
  </f>
</fs>
```

If the numeric value to be represented falls within a specific range (for example an address that spans several numbers), the *max* attribute may be used to supply an upper limit:

```
<fs>
  <f  name="houseNumber">
    <numeric  value="3418"  max="3440"/>
  </f>
  <f  name="streetName">
    <string>East Third Street</string>
  </f>
</fs>
```

It is also possible to specify that the numeric value (or values) represented should (or should not) be truncated. For example, assuming that the daily rainfall in mm is a feature of interest for some address, one might represent this by an encoding like the following:

```
<fs>
  <f  name="dailyRainFall">
    <numeric  value="0.0"  max="1.3"
      trunc="false"/>
  </f>
</fs>
```

This represents any of the infinite number of numeric values falling between 0 and 1.3; by contrast

```
<fs>
  <f  name="dailyRainFall">
    <numeric  value="0.0"  max="1.3"
      trunc="true"/>
  </f>
</fs>
```

represents only two possible values: 0 and 1.

Some communities of practice, notably those with a strong computer-science bias, prefer to dissociate the information on the value of the given feature from the specification of the data type that this value represents. In such cases, feature values can be provided directly as textual content of <f>, with the assumption that the data type is specified by the schema. The following is an example taken from ISO 24612, presenting the symbolic values for Active Voice and Simple Present Tense in the untyped form:

```
<fs>
  <f  name="voice">active</f>
  <f  name="tense">SimPre</f>
</fs>
```

As noted above, additional processing is necessary to ensure that appropriate values are supplied for particular features, for example to ensure that the feature `singular` is not given a value such as <symbol value="feminine"/>. There are two ways of attempting to ensure that only certain combinations of feature names and values are used. First, if the total number of legal combinations is relatively small, one can predefine all of them in a construct known as a *feature library*, and then reference the combination required using the *feats* attribute in the enclosing <fs> element, rather than give it explicitly. This method is suitable in the situation described above, since it requires specifying a total of only ten (5 + 3 + 2) combinations of features and values. Similarly, to ensure that only feature structures containing valid combinations of feature values are used, one can put definitions for all valid feature structures inside a *feature value library* (so called, since a feature structure may be the value of a feature). A total of 30 feature structures (5 × 3 × 2) is required to enumerate all the possible combinations of individual case, gender and number values in the preceding illustration. We discuss the use of such libraries and their representation in XML further in section *19.4. Feature Libraries and Feature-Value Libraries* below.

However, the most general method of attempting to ensure that only legal combinations of feature names and values are used is to provide a *feature-system declaration* discussed in *19.11. Feature System Declaration*.

Whether at the level of feature-system declarations, feature- and feature-value libraries, or individual features, it is possible to align both feature names and their values with standardized external data category repositories. [118] In the following example, both the feature part_of_speech and its value NN (standing for 'common noun') are aligned with the respective definitions provided by the CLARIN Concept Registry (CCR).

```
<fs>
  <f  name="part_of_speech"
    datcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3">
    <symbol  valueDatcat="http://hdl.handle.net/11459/CCR_C-1256_7ec6083c-23d4-224d-6f94-eecbe6861
      value="NN"/>
  </f>
<!-- ... -->
</fs>
```

Since the above representation takes up a lot of space and quickly becomes redundant and error-prone, it is possible to delegate the task of aligning with external repositories to elements such as <fLib>, <fvLib>, <fDecl>, or <fsDecl> to reduce the feature representation at hand and to increase its readability at the same time, as shown in the example below.

```
<fs>
<!-- ... -->
  <f  name="POS"  fVal="#common_noun"/>
<!-- ... -->
</fs>
```

[118] See section *10.5.2. Lexical View* for more discussion of the need and rationale for aligning the content of grammatical (and other) descriptions with standardized external taxonomies.

The value common_noun should best be listed (as an *xml:id*) either in a library of feature values (<fvLib>, see the following section) or in a <taxonomy> element.

19.4 Feature Libraries and Feature-Value Libraries

As the examples in the preceding section suggest, the direct encoding of feature structures can be verbose. Moreover, it is often the case that particular feature-value combinations, or feature structures composed of them, are re-used in different analyses. To reduce the size and complexity of the task of encoding feature structures, one may use the *feats* attribute of the <fs> element to point to one or more of the feature-value specifications for that element. This indirect method of encoding feature structures presumes that the <f> elements are assigned unique *xml:id* values, and are collected together in <fLib> elements (*feature libraries*). In the same way, feature values of whatever type can be collected together in <fvLib> elements (*feature-value libraries*). If a feature has as its value a feature structure or other value which is predefined in this way, the *fVal* attribute may be used to point to it, as discussed in the next section. The following elements are used for representing feature libraries and feature-value libraries:

`<fLib>` (feature library) assembles a library of <f> (feature) elements.

`<fvLib>` (feature-value library) assembles a library of reusable feature value elements (including complete feature structures).

For example, suppose a feature library for phonological feature specifications is set up as follows.

```
<fLib n="phonological features">
  <f xml:id="CNS1" name="consonantal">
    <binary value="true"/>
  </f>
  <f xml:id="CNS0" name="consonantal">
    <binary value="false"/>
  </f>
  <f xml:id="VOC1" name="vocalic">
    <binary value="true"/>
  </f>
  <f xml:id="VOC0" name="vocalic">
    <binary value="false"/>
  </f>
  <f xml:id="VOI1" name="voiced">
    <binary value="true"/>
  </f>
  <f xml:id="VOI0" name="voiced">
    <binary value="false"/>
  </f>
  <f xml:id="ANT1" name="anterior">
    <binary value="true"/>
  </f>
  <f xml:id="ANT0" name="anterior">
    <binary value="false"/>
  </f>
  <f xml:id="COR1" name="coronal">
    <binary value="true"/>
  </f>
  <f xml:id="COR0" name="coronal">
    <binary value="false"/>
  </f>
  <f xml:id="CNT1" name="continuant">
    <binary value="true"/>
  </f>
  <f xml:id="CNT0" name="continuant">
    <binary value="false"/>
```

```
  </f>
  <f  xml:id="STR1"  name="strident">
    <binary  value="true"/>
  </f>
  <f  xml:id="STR0"  name="strident">
    <binary  value="false"/>
  </f>
<!-- ... -->
</fLib>
```

Then the feature structures that represent the analysis of the phonological segments (phonemes) /t/, /d/, /s/, and /z/ may be defined as follows.

```
<fs  feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT0 #STR0"/>
<fs  feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT0 #STR0"/>
<fs  feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT1 #STR1"/>
<fs  feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT1 #STR1"/>
```

The preceding are but four of the 128 logically possible fully specified phonological segments using the seven binary features listed in the feature library. Presumably not all combinations of features correspond to phonological segments (there are no strident vowels, for example). The legal combinations, however, can be collected together, each one represented as an identifiable <fs> element within a *feature-value library*, as in the following example:

```
<fvLib  xml:id="fsl1"
  n="phonological segment definitions">
<!-- ... -->
  <fs  xml:id="T.DF"
    feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT0 #STR0"/>
  <fs  xml:id="D.DF"
    feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT0 #STR0"/>
  <fs  xml:id="S.DF"
    feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT1 #STR1"/>
  <fs  xml:id="Z.DF"
    feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT1 #STR1"/>
<!-- ... -->
</fvLib>
```

Once defined, these feature structure values can also be reused. Other <f> elements may invoke them by reference, using the *fVal* attribute; for example, one might use them in a feature value pair such as:

```
<f  name="dental-fricative"  fVal="#T.DF"/>
```

rather than expanding the hierarchy of the component phonological features explicitly.

The feature structure that concludes section *19.3. Other Atomic Feature Values* above, identifying the value of some part of speech to be a common noun, may be used in tandem with a feature-value library, which offers a way to encode a grammatical *tagset*, in this case containing labels for parts of speech:

```
<fvLib  n="POS values">
  <symbol  xml:id="common_noun"  value="NN"
    datcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3"/>
  <symbol  xml:id="proper_noun"  value="NP"
```

```
   datcat="http://hdl.handle.net/11459/CCR_C-1371_fbebd9ec-a7f4-9a36-d6e9-88ee16b944ae"/>
<!-- ... -->
</fvLib>
```

Such a feature-value library combines the standard short symbolic label for a part of speech (e.g., NN) with a mnemonic identifier that can be referenced by means of *fVal*, and with a persistent identifier, maintained in a public reference taxonomy repository together with the basic definition of the given concept.

Feature structures stored in the way presented in this section may also be associated with the text which they are intended to annotate, either by a link from the text (for example, using the TEI global *ana* attribute), or by means of stand-off annotation techniques (for example, using the TEI <link> element): see further section *19.10. Linking Text and Analysis* below.

Note that when features or feature structures are linked to in this way, the result is effectively a copy of the item linked to into the place from which it is linked. This form of linking should be distinguished from the phenomenon of *structure-sharing*, where it is desired to indicate that some part of an annotation structure appears simultaneously in two or more places within the structure. This kind of annotation should be represented using the <vLabel> element, as discussed in *19.6. Re-entrant Feature Structures* below.

19.5 Feature Structures as Complex Feature Values

Features may have complex values as well as atomic ones; the simplest such complex value is represented by supplying an <fs> element as the content of an <f> element, or (equivalently) by supplying the identifier of an <fs> element as the value for the *fVal* attribute on the <f> element. Structures may be nested as deeply as appropriate, using this mechanism. For example, an <fs> element may contain or point to an <f> element, which may contain or point to an <fs> element, which may contain or point to an <f> element, and so on.

To illustrate the use of complex values, consider the following simple model of a word, as a structure combining surface form information, a syntactic category, and semantic information. Each word analysis is represented as a <fs type='word'> element, containing three features named `surface`, `syntax`, and `semantics`. The first of these has an atomic string value, but the other two have complex values, represented as nested feature structures of types `category` and `act` respectively:

```
<fs type="word">
  <f name="surface">
    <string>love</string>
  </f>
  <f name="syntax">
    <fs type="category">
      <f name="pos">
        <symbol value="verb"/>
      </f>
      <f name="val">
        <symbol value="transitive"/>
      </f>
    </fs>
  </f>
  <f name="semantics">
    <fs type="act">
      <f name="rel">
        <symbol value="LOVE"/>
      </f>
    </fs>
  </f>
</fs>
```

This analysis does not tell us much about the meaning of the symbols `verb` or `transitive`. It might be preferable to replace these atomic feature values by feature structures. Suppose therefore that we maintain a feature-value library for each of the major syntactic categories (N, V, ADJ, PREP):

```
<fvLib  n="Major category definitions">
<!-- ... -->
  <fs  xml:id="N"  type="noun">
<!-- noun features defined here -->
  </fs>
  <fs  xml:id="V"  type="verb">
<!-- verb features defined here -->
  </fs>
</fvLib>
```

This library allows us to use shortcut codes (`N`, `V`, etc.) to reference a complete definition for the corresponding feature structure. Each definition may be explicitly contained within the <fs> element, as a number of <f> elements. Alternatively, the relevant features may be referenced by their identifiers, supplied as the value of the *feats* attribute, as in these examples:

```
<!-- ... -->
<fs xml:id="ADJ" type="adjective" feats="#F1 #F2"/>
<fs xml:id="PREP" type="preposition" feats="#F1 #F3"/>
<!-- ... -->
```

This ability to re-use feature definitions within multiple feature structure definitions is an essential simplification in any realistic example. In this case, we assume the existence of a feature library containing specifications for the basic feature categories like the following:

```
<fLib  n="categorial features">
  <f  xml:id="NN-1"  name="nominal">
    <binary  value="true"/>
  </f>
  <f  xml:id="NN-0"  name="nominal">
    <binary  value="false"/>
  </f>
  <f  xml:id="VV-1"  name="verbal">
    <binary  value="true"/>
  </f>
  <f  xml:id="VV-0"  name="verbal">
    <binary  value="false"/>
  </f>
<!-- ... -->
</fLib>
```

With such libraries in place, and assuming the availability of similarly predefined feature structures for transitivity and semantics, the preceding example could be considerably simplified:

```
<fs  type="word">
  <f  name="surface">
    <string>love</string>
  </f>
```

```
  <f  name="syntax">
    <fs  type="category">
      <f  name="pos"  fVal="#V"/>
      <f  name="val"  fVal="#TRNS"/>
    </fs>
  </f>
  <f  name="semantics">
    <fs  type="act">
      <f  name="rel"  fVal="#LOVE"/>
    </fs>
  </f>
</fs>
```

Although in principle the *fVal* attribute could point to any kind of feature value, its use is not recommended for simple atomic values.

19.6 Re-entrant Feature Structures

Sometimes the same feature value is required at multiple places within a feature structure, in particular where the value is only partially specified at one or more places. The <vLabel> element is provided as a means of labelling each such re-entrancy point:

`<vLabel>` (value label) represents the value part of a feature-value specification which appears at more than one point in a feature structure.

For example, suppose one wishes to represent noun-verb agreement as a single feature structure. Within the representation, the feature indicating (say) number appears more than once. To represent the fact that each occurrence is another appearance of the same feature (rather than a copy) one could use an encoding like the following:

```
<fs  xml:id="NVA">
  <f  name="nominal">
    <fs>
      <f  name="nm-num">
        <vLabel  name="L1">
          <symbol  value="singular"/>
        </vLabel>
      </f>
<!-- other nominal features -->
    </fs>
  </f>
  <f  name="verbal">
    <fs>
      <f  name="vb-num">
        <vLabel  name="L1"/>
      </f>
    </fs>
<!-- other verbal features -->
  </f>
</fs>
```

In the above encoding, the features named `vb-num` and `nm-num` exhibit structure sharing. Their values, given as `vLabel` elements, are understood to be references to the same point in the feature structure, which is labelled by their *name* attribute.

The scope of the names used to label re-entrancy points is that of the outermost <fs> element in which they appear. When a feature structure is imported from a feature value library, or referenced from elsewhere (for example by using the *fVal* attribute) the names of any sharing points it may contain are implicitly prefixed by the identifier used for

the imported feature structure, to avoid name clashes. Thus, if some other feature structure were to reference the <fs> element given in the example above, for example in this way:

```
<f  name="class"  fVal="#NVA"/>
```

then the labelled points in the example would be interpreted as if they had the name NVAL1.

19.7 Collections as Complex Feature Values

Complex feature values need not always be represented as feature structures. Multiple values may also be organized as sets, bags or multisets, or lists of atomic values of any type. The <vColl> element is provided to represent such cases:

<vColl> (collection of values) represents the value part of a feature-value specification which contains multiple values organized as a set, bag, or list.

A feature whose value is regarded as a set, bag, or list may have any positive number of values as its content, or none at all, (thus allowing for representation of the empty set, bag, or list). The items in a list are ordered, and need not be distinct. The items in a set are not ordered, and must be distinct. The items in a bag are neither ordered nor distinct. Sets and bags are thus distinguished from lists in that the order in which the values are specified does not matter for the former, but does matter for the latter, while sets are distinguished from bags and lists in that repetitions of values do not count for the former but do count for the latter.

If no value is specified for the *org* attribute, the assumption is that the <vColl> defines a list of values. If the <vColl> element is empty, the assumption is that it represents the null list, set, or bag.

To illustrate the use of the *org* attribute, suppose that a feature structure analysis is used to represent a genealogical tree, with the information about each individual treated as a single feature structure, like this:

```
<fs  xml:id="p027"  type="person">
  <f  name="forenames">
    <vColl>
      <string>Daniel</string>
      <string>Edouard</string>
    </vColl>
  </f>
  <f  name="mother"  fVal="#p002"/>
  <f  name="father"  fVal="#p009"/>
  <f  name="birthDate">
    <fs  type="date"  feats="#y1988 #m04 #d17"/>
  </f>
  <f  name="birthPlace"  fVal="#austintx"/>
  <f  name="siblings">
    <vColl  org="set">
      <fs  copyOf="#pnb005"/>
      <fs  copyOf="#prb001"/>
    </vColl>
  </f>
</fs>
```

In this example, the <vColl> element is first used to supply a list of 'name' feature values, which together constitute the 'forenames' feature. Other features are defined by reference to values which we assume are held in some external feature value library (not shown here). For example, the <vColl> element is used a second time to indicate that the persons's siblings should be regarded as constituting a set rather than a list. Each sibling is represented by a feature structure: in this example, each feature structure is a copy of one specified in the feature value library.

If a specific feature contains only a single feature structure as its value, the component features of which are organized as a set, bag, or list, it may be more convenient to represent the value as a <vColl> rather than as an <fs>. For example, consider the following encoding of the English verb form *sinks*, which contains an *agreement* feature whose value is a feature structure which contains *person* and *number* features with symbolic values.

```
<fs type="word">
  <f name="category">
    <symbol value="verb"/>
  </f>
  <f name="tense">
    <symbol value="present"/>
  </f>
  <f name="agreement">
    <fs>
      <f name="person">
        <symbol value="third"/>
      </f>
      <f name="number">
        <symbol value="singular"/>
      </f>
    </fs>
  </f>
</fs>
```

If the names of the features contained within the *agreement* feature structure are of no particular significance, the following simpler representation may be used:

```
<fs type="word">
  <f name="category">
    <symbol value="verb"/>
  </f>
  <f name="tense">
    <symbol value="present"/>
  </f>
  <f name="agreement">
    <vColl org="set">
      <symbol value="third"/>
      <symbol value="singular"/>
    </vColl>
  </f>
</fs>
```

The <vColl> element is also useful in cases where an analysis has several components. In the following example, the French word *auxquels* has a two-part analysis, represented as a list of two values. The first specifies that the word contains a preposition; the second that it contains a masculine plural relative pronoun:

```
<fs>
  <f name="lex">
    <symbol value="auxquels"/>
  </f>
  <f name="maf">
    <vColl org="list">
      <fs>
        <f name="cat">
          <symbol value="prep"/>
        </f>
      </fs>
      <fs>
        <f name="cat">
```

```
        <symbol value="pronoun"/>
      </f>
      <f name="kind">
        <symbol value="rel"/>
      </f>
      <f name="num">
        <symbol value="pl"/>
      </f>
      <f name="gender">
        <symbol value="masc"/>
      </f>
    </fs>
  </vColl>
 </f>
</fs>
```

The set, bag, or list which has no members is known as the null (or empty) set, bag, or list. A <vColl> element with no content and with no value for its *feats* attribute is interpreted as referring to the null set, bag, or list, depending on the value of its *org* attribute.

If, for example, the individual described by the feature structure with identifier `p027` (above) had no siblings, we might specify the *siblings* feature as follows.

```
<f name="siblings">
 <vColl org="set"/>
</f>
```

A <vColl> element may also collect together one or more other <vColl> elements, if, for example one of the members of a set is itself a set, or if two lists are concatenated together. Note that such collections pay no attention to the contents of the nested <vColl> elements: if it is desired to produce the union of two sets, the <vMerge> element discussed below should be used to make a new collection from the two sets.

19.8 Feature Value Expressions

It is sometimes desirable to express the value of a feature as the result of an operation over some other value (for example, as 'not green', or as 'male or female', or as the concatenation of two collections). Three special purpose elements are provided to represent disjunctive alternation, negation, and collection of values:

`<vAlt>` (value alternation) represents the value part of a feature-value specification which contains a set of values, only one of which can be valid.

`<vNot>` (value negation) represents a feature value which is the negation of its content.

`<vMerge>` (merged collection of values) represents a feature value which is the result of merging together the feature values contained by its children, using the organization specified by the *org* attribute.

19.8.1 Alternation

The <vAlt> element can be used wherever a feature value can appear. It contains two or more feature values, any one of which is to be understood as the value required. Suppose, for example, that we are using a feature system to describe residential property, using such features as *number.of.bathrooms*. In a particular case, we might wish to represent uncertainty as to whether a house has two or three bathrooms. As we have already shown, one simple way to represent this would be with a numeric maximum:

```
<f name="number.of.bathrooms">
 <numeric value="2" max="3"/>
</f>
```

A more general way would be to represent the alternation explicitly, in this way:

```
<f  name="number.of.bathrooms">
  <vAlt>
    <numeric  value="2"/>
    <numeric  value="3"/>
  </vAlt>
</f>
```

The <vAlt> element represents alternation over feature values, not feature-value pairs. If therefore the uncertainty relates to two or more feature value specifications, each must be represented as a feature structure, since a feature structure can always appear where a value is required. For example, suppose that it is uncertain as to whether the house being described has two bathrooms or two bedrooms, a structure like the following may be used:

```
<f  name="rooms">
  <vAlt>
    <fs>
      <f  name="number.of.bathrooms">
        <numeric  value="2"/>
      </f>
    </fs>
    <fs>
      <f  name="number.of.bedrooms">
        <numeric  value="2"/>
      </f>
    </fs>
  </vAlt>
</f>
```

Note that alternation is always regarded as *exclusive*: in the case above, the implication is that having two bathrooms excludes the possibility of having two bedrooms and vice versa. If inclusive alternation is required, a <vColl> element may be included in the alternation as follows:

```
<f  name="rooms">
  <vAlt>
    <fs>
      <f  name="number.of.bathrooms">
        <numeric  value="2"/>
      </f>
    </fs>
    <fs>
      <f  name="number.of.bedrooms">
        <numeric  value="2"/>
      </f>
    </fs>
    <vColl>
      <fs>
        <f  name="number.of.bathrooms">
          <numeric  value="2"/>
        </f>
      </fs>
      <fs>
        <f  name="number.of.bedrooms">
          <numeric  value="2"/>
```

```
      </f>
     </fs>
   </vColl>
  </vAlt>
</f>
```

This analysis indicates that the property may have two bathrooms, two bedrooms, or both two bathrooms and two bedrooms.

As the previous example shows, the <vAlt> element can also be used to indicate alternations among values of features organized as sets, bags or lists. Suppose we use a feature `selling.points` to describe items that are mentioned to enhance a property's sales value, such as whether it has a pool or a good view. Now suppose for a particular listing, the selling points include an alarm system and a good view, and either a pool or a jacuzzi (but not both). This situation could be represented, using the <vAlt> element, as follows.

```
<fs  type="real_estate_listing">
  <f  name="selling.points">
    <vColl  org="set">
      <string>alarm system</string>
      <string>good view</string>
      <vAlt>
        <string>pool</string>
        <string>jacuzzi</string>
      </vAlt>
    </vColl>
  </f>
</fs>
```

Now suppose the situation is like the preceding except that one is also uncertain whether the property has an alarm system or a good view. This can be represented as follows.

```
<fs  type="real_estate_listing">
  <f  name="selling.points">
    <vColl  org="set">
      <vAlt>
        <string>alarm system</string>
        <string>good view</string>
      </vAlt>
      <vAlt>
        <string>pool</string>
        <string>jacuzzi</string>
      </vAlt>
    </vColl>
  </f>
</fs>
```

If a large number of ambiguities or uncertainties need to be represented, involving a relatively small number of features and values, it is recommended that a stand-off technique, for example using the general-purpose <alt> element discussed in section *17.8. Alternation* be used, rather than the special-purpose <vAlt> element.

19.8.2 Negation

The <vNot> element can be used wherever a feature value can appear. It contains any feature value and returns the complement of its contents. For example, the feature *number.of.bathrooms* in the following example has any whole numeric value other than 2:

```
<f  name="number.of.bathrooms">
  <vNot>
    <numeric  value="2"/>
  </vNot>
</f>
```

Strictly speaking, the effect of the <vNot> element is to provide the complement of the feature values it contains, rather than their negation. If a feature system declaration is available which defines the possible values for the associated feature, then it is possible to say more about the negated value. For example, suppose that the available values for the feature `case` are declared to be nominative, genitive, dative, or accusative, whether in a TEI feature system declaration or by some other means. Then the following two specifications are equivalent:

```
 (i) <f  name="case">
  <vNot>
    <symbol  value="genitive"/>
  </vNot>
</f>
(ii)
<f  name="case">
  <vAlt>
    <symbol  value="nominative"/>
    <symbol  value="dative"/>
    <symbol  value="accusative"/>
  </vAlt>
</f>
```

If however no such system declaration is available, all that one can say about a feature specified via negation is that its value is something other than the negated value.

Negation is always applied to a feature value, rather than to a feature-value pair. The negation of an atomic value is the set of all other values which are possible for the feature.

Any kind of value can be negated, including collections (represented by a <vColl> elements) or feature structures (represented by <fs> elements). The negation of any complex value is understood to be the set of values which cannot be unified with it. Thus, for example, the negation of the feature structure F is understood to be the set of feature structures which are not unifiable with F. In the absence of a constraint mechanism such as the Feature System Declaration, the negation of a collection is anything that is not unifiable with it, including collections of different types and atomic values. It will generally be more useful to require that the organization of the negated value be the same as that of the original value, for example that a negated set is understood to mean the set which is a complement of the set, but such a requirement cannot be enforced in the absence of a constraint mechanism.

19.8.3 Collection of Values

The <vMerge> element can be used wherever a feature value can appear. It contains two or more feature values, all of which are to be collected together. The organization of the resulting collection is specified by the value of the *org* attribute, which need not necessarily be the same as that of its constituent values if these are collections. For example, one can change a list to a set, or vice versa.

As an example, suppose that we wish to represent the range of possible values for a feature 'genders' used to describe some language. It would be natural to represent the possible values as a set, using the <vColl> element as in the following example:

```
<fs>
  <f  name="genders">
    <vColl  org="set">
      <symbol  value="masculine"/>
```

```
      <symbol value="feminine"/>
    </vColl>
  </f>
</fs>
```

Suppose however that we discover for some language it is necessary to add a new possible value, and to treat the value of the feature as a list rather than as a set. The <vMerge> element can be used to achieve this:

```
<fs>
  <f name="genders">
    <vMerge org="list">
      <vColl org="set">
        <symbol value="masculine"/>
        <symbol value="feminine"/>
      </vColl>
      <symbol value="neuter"/>
    </vMerge>
  </f>
</fs>
```

19.9 Default Values

The value of a feature may be underspecified in a number of different ways. It may be null, unknown, or uncertain with respect to a range of known possibilities, as well as being defined as a negation or an alternation. As previously noted, the specification of the range of known possibilities for a given feature is not part of the current specification: in the TEI scheme, this information is conveyed by the *feature system declaration*. Using this, or some other system, we might specify (for example) that the range of values for an element includes symbols for masculine, feminine, and neuter, and that the default value is neuter. With such definitions available to us, it becomes possible to say that some feature takes the default value, or some unspecified value from the list. The following special element is provided for this purpose:

`<default>` (default feature value) represents the value part of a feature-value specification which contains a defaulted value.

The value of an empty <f> element which also lacks an *fVal* attribute is understood to be the most general case, i.e. any of the available values. Thus, assuming the feature system defined above, the following two representations are equivalent.

```
<f name="gender"/>
<f name="gender">
  <vAlt>
    <symbol value="feminine"/>
    <symbol value="masculine"/>
    <symbol value="neuter"/>
  </vAlt>
</f>
```

If, however, the value is explicitly stated to be the default one, using the <default> element, then the following two representations are equivalent:

```
<f name="gender">
  <default/>
</f>
```

```
<f  name="gender">
  <symbol  value="neuter"/>
</f>
```

Similarly, if the value is stated to be the negation of the default, then the following two representations are equivalent:

```
<f  name="gender">
  <vNot>
    <default/>
  </vNot>
</f>
```

```
<f  name="gender">
  <vAlt>
    <symbol  value="feminine"/>
    <symbol  value="masculine"/>
  </vAlt>
</f>
```

19.10 Linking Text and Analysis

Text elements can be linked with feature structures using any of the linking methods discussed elsewhere in these Guidelines (see for example sections *18.2. Global Attributes for Simple Analyses* and *18.4. Linguistic Annotation*). In the simplest case, the *ana* attribute may be used to point from any element to an annotation of it, as in the following example:

```
<s  n="00741">
  <w  ana="#at0">The</w>
  <w  ana="#ajs">closest</w>
  <w  ana="#pnp">he</w>
  <w  ana="#vvd">came</w>
  <w  ana="#prp">to</w>
  <w  ana="#nn1">exercise</w>
  <w  ana="#vbd">was</w>
  <w  ana="#to0">to</w>
  <w  ana="#vvi">open</w>
  <w  ana="#crd">one</w>
  <w  ana="#nn1">eye</w>
  <phr  ana="#av0">
    <w>every</w>
    <w>so</w>
    <w>often</w>
  </phr>
  <c  ana="#pun">,</c>
  <w  ana="#cjs">if</w>
  <w  ana="#pni">someone</w>
  <w  ana="#vvd">entered</w>
  <w  ana="#at0">the</w>
  <w  ana="#nn1">room</w>
<!-- ... -->
</s>
```

The values specified for the *ana* attribute reference components of a feature-structure library, which represents all of the grammatical structures used by this encoding scheme. (For illustrative purposes, we cite here only the structures needed for the first six words of the sample sentence):

```
<fvLib xml:id="C6" n="Claws 6 tags">
<!-- ... -->
  <fs xml:id="ajs"
    type="grammatical_structure" feats="#wj #ds"/>
  <fs xml:id="at0"
    type="grammatical_structure" feats="#wl"/>
  <fs xml:id="pnp"
    type="grammatical_structure" feats="#wr #rp"/>
  <fs xml:id="vvd"
    type="grammatical_structure" feats="#wv #bv #fd"/>
  <fs xml:id="prp"
    type="grammatical_structure" feats="#wp #bp"/>
  <fs xml:id="nnn"
    type="grammatical_structure" feats="#wn #tc #ns"/>
<!-- ... -->
</fvLib>
```

The components of each feature structure in the library are referenced in much the same way, using the *feats* attribute to identify one or more <f> elements in the following feature library (again, only a few of the available features are quoted here):

```
<fLib>
<!-- ... -->
  <f xml:id="fl-bv" name="verbbase">
    <symbol value="main"/>
  </f>
  <f xml:id="fl-bp" name="prepbase">
    <symbol value="lexical"/>
  </f>
  <f xml:id="fl-ds" name="degree">
    <symbol value="superlative"/>
  </f>
  <f xml:id="fl-fd" name="verbform">
    <symbol value="ed"/>
  </f>
  <f xml:id="fl-ns" name="number">
    <symbol value="singular"/>
  </f>
  <f xml:id="fl-rp" name="prontype">
    <symbol value="personal"/>
  </f>
  <f xml:id="fl-tc" name="nountype">
    <symbol value="common"/>
  </f>
  <f xml:id="fl-wj" name="class">
    <symbol value="adjective"/>
  </f>
  <f xml:id="fl-wl" name="class">
    <symbol value="article"/>
  </f>
  <f xml:id="fl-wn" name="class">
    <symbol value="noun"/>
```

```
  </f>
  <f  xml:id="fl-wp"  name="class">
    <symbol  value="preposition"/>
  </f>
  <f  xml:id="fl-wr"  name="class">
    <symbol  value="pronoun"/>
  </f>
  <f  xml:id="fl-wv"  name="class">
    <symbol  value="verb"/>
  </f>
<!-- ... -->
</fLib>
```

Alternatively, a stand-off technique may be used, as in the following example, where a <linkGrp> element is used to link selected characters in the text *Caesar seized control* with their phonological representations.

```
<s>
  <w  xml:id="S1W1">
    <c  xml:id="S1W1C1">C</c>ae<c  xml:id="S1W1C2">s</c>ar</w>
  <w  xml:id="S1W2">
    <c  xml:id="S1W2C1">s</c>ei<c  xml:id="S1W2C2">z</c>e<c  xml:id="S1W2C3">d</c>
  </w>
  <w  xml:id="S1W3">con<c  xml:id="S1W3C1">t</c>rol</w>.

</s>
<fvLib  xml:id="FSL1"
  n="phonological segment definitions">
<!-- as in previous example -->
</fvLib>
<linkGrp  type="phonology">
<!-- ... -->
  <link  target="#S.DF #S1W3C1"/>
  <link  target="#Z.DF #S1W2C3"/>
  <link  target="#S.DF #S1W2C1"/>
  <link  target="#Z.DF #S1W2C2"/>
<!-- ... -->
</linkGrp>
```

As this example shows, a stand-off solution requires that every component to be linked to must be addressable in some way, by means of an XPointer. To handle the POS tagging example above, for example, each annotated element might be given an identifier of some sort, as follows:

```
<s  xml:id="mds09"  n="00741">
  <w  xml:id="mds0901">The</w>
  <w  xml:id="mds0902">closest</w>
  <w  xml:id="mds0903">he</w>
  <w  xml:id="mds0904">came</w>
  <w  xml:id="mds0905">to</w>
  <w  xml:id="mds0906">exercise</w>
<!-- ... -->
</s>
```

It would then be possible to link each word to its intended annotation in the feature library quoted above, as follows:

```
<linkGrp  type="POS-codes">
<!-- ... -->
  <link  target="#mds0901 #at0"/>
  <link  target="#mds0902 #ajs"/>
  <link  target="#mds0903 #pnp"/>
  <link  target="#mds0904 #vvd"/>
  <link  target="#mds0905 #prp"/>
  <link  target="#mds0906 #nn1"/>
  <link  target="#mds0907 #vbd"/>
  <link  target="#mds0908 #to0"/>
  <link  target="#mds0909 #vvi"/>
  <link  target="#mds0910 #crd"/>
<!-- ... -->
</linkGrp>
```

19.11 Feature System Declaration

The Feature System Declaration (FSD) is intended for use in conjunction with a TEI-conforming text that makes use of <fs> (that is, feature structure) elements. The FSD serves three purposes:

- the encoder can list all of the feature names and feature values and give a prose description as to what each represents.
- the encoder can define what it means to be a well-formed feature structure, and define constraints which may be used to determine whether a particular feature structure is *valid* relative to a given theory stated in typed feature logic. These may involve constraints on the range of a feature value, constraints on what features are valid within certain types of feature structures, or constraints that prevent the co-occurrence of certain feature-value pairs.
- the encoder can define the intended interpretation of underspecified feature structures. This involves defining default values (whether literal or computed) for missing features.

The scheme described in this chapter may be used to document any feature structure system, but is primarily intended for use with the feature structure representation defined by the ISO 24610-1:2006 standard, which corresponds with the recommendations presented in these Guidelines, *19. Feature Structures*. This chapter relies upon, but does not reproduce, formal definitions and descriptions presented more thoroughly in the ISO standard, which should be consulted in case of ambiguity or uncertainty.

The FSD serves an important function in documenting precisely what the encoder intended by the system of feature structure markup used in an XML-encoded text. The FSD is also an important resource which standardizes the rules of inference used by software to validate the feature structure markup in a text, and to infer the full interpretation of underspecified feature structures.

The reader should be aware the terminology used in this document does not always closely follow conventional practice in formal logic, and may also diverge from practice in some linguistic applications of typed feature structures. In particular, the term 'interpretation' when applied to a feature structure is not an interpretation in the model-theoretic sense, but is instead a minimally informative (or equivalently, most general) extension of that feature structure that is consistent with a set of constraints declared by an FSD. In linguistic application, such a system of constraints is the principal means by which the grammar of some natural language is expressed. There is a great deal of disagreement as to what, if any, model-theoretic interpretation feature structures have in such applications, but the status of this formal kind of interpretation is not germane to the present document. Similarly, the term 'valid' is used here as elsewhere in these Guidelines to identify the syntactic state of well-formedness in the sense defined by the logic of typed feature structures itself, as distinct from and in addition to the 'well-formedness' that pertains at the level of this encoding standard. No appeal to any notion from formal semantics should be inferred.

We begin by describing how an encoded text is associated with one or more feature system declarations. The second, third, and fourth sections describe the overall structure of a feature system declaration and give details of how to encode its components. The final section offers a full example; fuller discussion of the reasoning behind FSDs and another complete example are provided in **?**.

19.11.1 Linking a TEI Text to Feature System Declarations

In order for application software to use feature system declarations to aid in the automatic interpretation of encoded texts, or even for human readers to find the appropriate declarations which document the feature system used in markup, there must be a formal link from the encoded texts to the declarations. However, the schema which declares the syntax of the Feature System itself should be kept distinct from the feature structure schema, which is an application of that system.

A document containing typed feature structures may simply include a feature system declaration documenting those feature structures. A more usual scenario, however, is that the same feature system declaration (or parts of it) will be shared by many documents. In either case, an <fsDecl> element for each distinct type of feature structure used must be provided and associated with the type, which is the value used within each feature structure for its *type* attribute.

When the module defined in this chapter is included in an XML schema, the following elements become available via the `model.fsdDeclPart` class:

`<fsdDecl>` (feature system declaration) provides a feature system declaration comprising one or more feature structure declarations or feature structure declaration links.

`model.fsdDeclPart` groups elements which can occur as direct children of <fsdDecl>.

fLib	(feature library) assembles a library of <f> (feature) elements.
fsDecl	(feature structure declaration) declares one type of feature structure.
fsdLink	(feature structure declaration link) associates the name of a typed feature structure with a feature structure declaration for it.
fvLib	(feature-value library) assembles a library of reusable feature value elements (including complete feature structures).

The <fsdDecl> element serves as a wrapper for declaring feature systems and may be supplied either within the header of a standard TEI document, or as a standalone document in its own right. It contains one or more <fsdLink> or <fsDecl> elements and may hold several <fLib> or <fvLib> as well.

For example, suppose that a document `doc.xml` contains feature structures of two types: gpsg and lex. We might simply embed an <fsDecl> element for each within the header attached to the document as follows:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
<!-- example -->
    </fileDesc>
    <encodingDesc>
<!-- ... -->
      <fsdDecl>
        <fsDecl  type="gpsg">
<!-- information about this type -->
        </fsDecl>
        <fsDecl  type="lex">
<!-- information about this type -->
        </fsDecl>
      </fsdDecl>
<!-- ... -->
    </encodingDesc>
  </teiHeader>
  <text>
    <body>
<!-- ... -->
      <fs  type="lex">
<!-- an instance of the typed feature structure "lex" -->
      </fs>
```

```
<!-- ... -->
   </body>
  </text>
</TEI>
```

In this case there is an implicit link between the <fs> element and the corresponding <fsDecl> element because they share the same value for their *type* attribute and appear within the same document. This is a short cut for the more general case which requires a more explicit link provided by means of the <fsdLink> element, as demonstrated below.

Now suppose that we wish to create a second document which includes feature structures of the same type. Rather than duplicate the corresponding declarations, we will need to provide a means of pointing to them from this second document. The easiest[119] way of accomplishing this is to add an XML identifier to each <fsDecl> element in `example.xml`:

```
<fsdDecl>
  <fsDecl  type="gpsg"  xml:id="GPSG">
<!-- information about this type -->
  </fsDecl>
  <fsDecl  type="lex"  xml:id="LEX">
<!-- information about this type -->
  </fsDecl>
</fsdDecl>
```

(Although in this case the XML identifier is simply an uppercase version of the type name, there is no necessary connection between the two names. The only requirement is that the XML identifier conform to the standards required for identifiers, and that it be unique within the document containing it.)

In the <fsdDecl> for the second document, we can now include pointers to the <fsDecl> elements in the first:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
<!-- doc2 -->
    </fileDesc>
    <encodingDesc>
<!-- ... -->
      <fsdDecl>
        <fsdLink  type="gpsg"
          target="example.xml#GPSG"/>
        <fsdLink  type="lexx"
          target="example.xml#LEX"/>
      </fsdDecl>
<!-- ... -->
    </encodingDesc>
  </teiHeader>
  <text>
    <body>
<!-- ... -->
      <fs  type="lexx">
<!-- an instance of the typed feature structure "lex" -->
      </fs>
<!-- ... -->
    </body>
```

[119] Ways of pointing to components of a TEI document without using an XML identifier are discussed in *17.2.1. Pointing Elsewhere*

```
  </text>
</TEI>
```

Note that in doc2.xml there is no requirement for the local name for a given type of feature structures to be the same as that used by example.xml. We assume in this encoding that the type called lexx in doc2.xml is declared as having identical constraints and other properties to those declared for the type called lex in example.xml.

An <fsdDecl> may be given, as above, within the encoding description of the <teiHeader> element of a TEI document containing typed feature structures. Alternatively, it may appear independently of any feature structures, as a document in its own right with its own <teiHeader>. These options are both possible because the element is a member of both the model.encodingDescPart class and the model.resource class.

The current recommendations provide no way of enforcing uniqueness of the *type* values among <fsdDecl> elements, nor of requiring that every *type* value specified on an <fs> element be also declared on an <fsdDecl> element. Encoders requiring such constraints (which might have some obvious utility in assisting the consistency and accuracy of tagging) are recommended to develop tools to enforce them, using such mechanisms as Schematron assertions.

19.11.2 The Overall Structure of a Feature System Declaration

A feature system declaration contains one or more feature structure declarations, each of which has up to three parts: an optional description (which gives a prose comment on what that type of feature structure encodes), an obligatory set of feature declarations (which specify range constraints and default values for the features in that type of structure), and optional feature structure constraints (which specify co-occurrence restrictions on feature values).

<fsDescr> (feature system description (in FSD)) describes in prose what is represented by the type of feature structure declared in the enclosing fsDecl.

<fDecl> (feature declaration) declares a single feature, specifying its name, organization, range of allowed values, and optionally its default value.

<fsConstraints> (feature-structure constraints) specifies constraints on the content of valid feature structures.

Feature declarations and feature structure constraints are described in the next two sections. Note that the specification of similar <fsDecl> elements can be simplified by devising an inheritance hierarchy for the feature structure types. Each <fsDecl> element may name one or more 'basetypes' from which it inherits feature declarations and constraints (these are often called 'supertypes'). For instance, suppose that <fsDecl type="Basic"> contains <fDecl name="One"> and <fDecl name="Two">, and that <fsDecl type="Derived" baseTypes="Basic"> contains just <fDecl name="Three">. Then any instance of <fs type="Derived"> must include all three features. This is because <fsDecl type="Derived"> inherits the two feature declarations from <fsDecl type="Basic"> when it specifies a base type of Basic.

The following sample shows the overall structure of a complete feature structure declaration:

```
<fsDecl type="SomeName">
  <fsDescr>Describes what this type of fs represents</fsDescr>
  <fDecl name="featureOne">
<!-- The declaration for featureOne -->
  </fDecl>
  <fDecl name="featureTwo">
<!-- The declaration for featureTwo -->
  </fDecl>
  <fsConstraints>
<!-- The feature structure constraints go here -->
  </fsConstraints>
</fsDecl>
```

The attribute *baseTypes* gives the name of one or more types from which this type inherits feature specifications and constraints; if this type includes a feature specification with the same name as one inherited from any of the

types specified by this attribute, or if more than one specification of the same name is inherited, then the possible values of that feature is determined by unification. Similarly, the set of constraints applicable is derived by conjoining those specified explicitly within this element with those implied by the *baseTypes* attribute. When no base type is specified, no feature specification or constraint is inherited.

Although the present standard does provide for default feature values, feature inheritance is defined to be monotonic.

The process of combining constraints may result in a contradiction, for example if two specifications for the same feature specify disjoint ranges of values, and at least one such specification is mandatory. In such a case, there is no valid feature structure of the type being defined.

Every type specified by *baseTypes* must be a single word which is a legal XML name; for example, they cannot include whitespace or begin with digits. Multiple base types are separated with spaces, e.g. <fsDecl type="Sub" baseTypes="Super1 Super2">.

19.11.3 Feature Declarations

Each feature is declared in an <fDecl> element whose *name* attribute identifies the feature being declared; this matches the *name* attribute of the <f> elements it declares. An <fDecl> has three parts: an optional prose description (which should explain what the feature and its values represent), an obligatory range specification (which declares what values the feature is allowed to have), and an optional default specification (which declares what default value should be supplied when the named feature does not appear in an <fs>). If, in a feature structure, a feature:

- is not optional (i.e., is obligatory),
- has no value provided, or the value <default> is provided (see ISO 24610-1, Subclause 5.10, Default Values, and
- either has no default specified, or has conditional defaults, none of the conditions on which is met,

then the value of this feature in the feature structure's most general valid extension is the most general value provided in its <vRange>, in the case of a unit organization, or the singleton set, bag, or list containing that element, in the case of a complex organization. If the feature:

- is optional,
- has no value provided, or the value <default> is provided, and
- either has a default specified, or has conditional defaults, one of the conditions on which is met,

then this feature does have a value in the feature structure's most general valid extension when it exists, namely the default value that pertains.

It is possible that a feature structure will not have a valid extension because the default value that pertains to a feature is not consistent with that feature's declared range. Additional tools are required for the enforcement of such criteria.

The following elements are used in feature system declarations:

`<fDecl>` (feature declaration) declares a single feature, specifying its name, organization, range of allowed values, and optionally its default value.

- `@name` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), indicating the name of the feature being declared; matches the *name* attribute of <f> elements in the text.
- `@optional` indicates whether or not the value of this feature may be present.

`<fDescr>` (feature description (in FSD)) describes in prose what is represented by the feature being declared and its values.

`<vRange>` (value range) defines the range of allowed values for a feature, in the form of an <fs>, <vAlt>, or primitive value; for the value of an <f> to be valid, it must be subsumed by the specified range; if the <f> contains multiple values (as sanctioned by the *org* attribute), then each value must be subsumed by the <vRange>.

`<vDefault>` (value default) declares the default value to be supplied when a feature structure does not contain an instance of <f> for this name; if unconditional, it is specified as one (or, depending on the value of the *org* attribute of the enclosing <fDecl>) more <fs> elements or primitive values; if conditional,

it is specified as one or more <if> elements; if no default is specified, or no condition matches, the value none is assumed.

`<if>` defines a conditional default value for a feature; the condition is specified as a feature structure, and is met if it subsumes the feature structure in the text for which a default value is sought.

`<then>` separates the condition from the default in an <if>, or the antecedent and the consequent in a <cond> element.

The logic for validating feature values and for matching the conditions for supplying default values is based on the operation of *subsumption*. Subsumption is a standard operation in feature-structure-based formalisms. Informally, a feature structure FS subsumes all feature structures that are at least as informative as itself; that is, all feature structures that specify all of the feature values that FS does with values that are subsumed by the values that FS has, and that have all of the re-entrancies (see *19.6. Re-entrant Feature Structures*) that FS does. (**?**; see also **?** and **?**) A more formal definition is provided in ISO 24610-1:2006 .

Following the spirit of the informal definition above, we can extend subsumption in a straightforward way to cover alternation, negation, special primitive values, and the use of attributes in the markup. For instance, a <vAlt> containing the value v subsumes v. The negation of a value v (represented by means of the <vNot> element discussed in section *19.8.2. Negation*) subsumes any value that is not v; for example `<vNot><numeric value='0'/></vNot>` subsumes any numeric value other than zero. The value <fs type="X"/> subsumes any feature structure of type X, even if it is not valid.

As an example of feature declarations, consider the following extract from Gazdar et al.'s *Generalized Phrase Structure Grammar*. In the appendix to their book, they propose a feature system for English of which this is just a sampling:

```
feature    value range
INV        {+, -}
CONJ       {and, both, but, either, neither, nor, or, NIL}
COMP       {for, that, whether, if, NIL}
AGR        CAT
PFORM      {to, by, for, ...}
```

```
Feature specification defaults
FSD 1:  [-INV]
FSD 2:  ~[CONJ]
FSD 9:  [INF, +SUBJ] --> [COMP for]
```

The INV feature, which encodes whether or not a sentence is inverted, allows only the values plus (+) and minus (-). If the feature is not specified, then the default rule (FSD 1 above) says that a value of minus is always assumed. The feature declaration for this feature would be encoded as follows:

```
<fDecl name="INV">
  <fDescr>inverted sentence</fDescr>
  <vRange>
    <vAlt>
      <binary value="true"/>
      <binary value="false"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>
```

The value range is specified as an alternation (more precisely, an exclusive disjunction), which can be represented by the <binary> feature value. That is, the value must be either true or false, but cannot be both or neither.

The CONJ feature indicates the surface form of the conjunction used in a construction. The ~in the default rule (see FSD 2 above) represents negation. This means that by default the feature is not applicable, in other words, no conjunction is taking place. Note that CONJ not being present is distinct from CONJ being present but having the NIL value allowed in the value range. In their analysis, NIL means that the phenomenon of conjunction is taking place but there is no explicit conjunction in the surface form of the sentence. The feature declaration for this feature would be encoded as follows:

```
<fDecl name="CONJ">
  <fDescr>surface form of the conjunction</fDescr>
  <vRange>
    <vAlt>
      <symbol value="and"/>
      <symbol value="both"/>
      <symbol value="but"/>
      <symbol value="either"/>
      <symbol value="neither"/>
      <symbol value="nor"/>
      <symbol value="or"/>
      <symbol value="NIL"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>
```

Note that the <vDefault> is not strictly necessary in this case, since the binary value of false only serves to convey the information that the feature has no other legitimate value.

The COMP feature indicates the surface form of the complementizer used in a construction. In value range, it is analogous to CONJ. However, its default rule (see FSD 9 above) is conditional. It says that if the verb form is infinitival (the VFORM feature is not mentioned in the rule since it is the only feature that can take INF as a value), and the construction has a subject, then a *for* complement must be used. For instance, to make John the subject of the infinitive in *It is necessary to go,* a *for* complement must be used; that is, *It is necessary for John to go.* The feature declaration for this feature would be encoded as follows:

```
<fDecl name="COMP">
  <fDescr>surface form of the complementizer</fDescr>
  <vRange>
    <vAlt>
      <symbol value="for"/>
      <symbol value="that"/>
      <symbol value="whether"/>
      <symbol value="if"/>
      <symbol value="NIL"/>
    </vAlt>
  </vRange>
  <vDefault>
    <if>
      <fs>
        <f name="VFORM">
          <symbol value="INF"/>
        </f>
        <f name="SUBJ">
```

```
        <binary value="true"/>
      </f>
    </fs>
    <then/>
    <symbol value="for"/>
  </if>
 </vDefault>
</fDecl>
```

The AGR feature stores the features relevant to subject-verb agreement. Gazdar et al. specify the range of this feature as CAT. This means that the value is a *category*, which is their term for a feature structure. This is actually too weak a statement. Not just any feature structure is allowable here; it must be a feature structure for agreement (which is defined in the complete example at the end of the chapter to contain the features of person and number). The following feature declaration encodes this constraint on the value range:

```
<fDecl name="AGR">
 <fDescr>agreement for person and number</fDescr>
 <vRange>
  <fs type="Agreement"/>
 </vRange>
</fDecl>
```

That is, the value must be a feature structure of type Agreement. The complete example at the end of this chapter includes the <fsDecl type="Agreement"> which includes <fDecl name="PERS"> and <fDecl name="NUM">.

The PFORM feature indicates the surface form of the preposition used in a construction. Since PFORM is specified above as an open set, <string> is used in the range specification below rather than <symbol>.

```
<fDecl name="PFORM">
 <fDescr>word form of a preposition</fDescr>
 <vRange>
  <vNot>
   <string/>
  </vNot>
 </vRange>
</fDecl>
```

This example makes use of a negated value: `<vNot><string/></vNot>` subsumes any string that is not the empty string.

For the reduced feature structure that concludes section *19.3. Other Atomic Feature Values* above and identifies the value of some part of speech to be a common noun, it is possible to align the concept of *part of speech* with its definition and persistent identifier using the *targetDatcat* attribute, which connects the modeled XML object with the appropriate locus in a reference taxonomy, as shown below:

```
<fDecl name="POS"
 targetDatcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3">
 <fDescr>part of speech (morphosyntactic category)</fDescr>
 <vRange>
  <vAlt>
   <symbol value="NN"
    datcat="http://hdl.handle.net/11459/CCR_C-1256_7ec6083c-23d4-224d-6f94-eecbe6861545"/>
   <symbol value="NP"
    datcat="http://hdl.handle.net/11459/CCR_C-1371_fbebd9ec-a7f4-9a36-d6e9-88ee16b944ae"/>
```

```
<!-- ... -->
    </vAlt>
  </vRange>
</fDecl>
```

The above example declares the feature 'POS' as instantiating the corresponding concept defined in a reference taxonomy or ontology, and defines the range of values of the feature at hand by listing the appropriate alternatives, together with their external persistent identifiers.

Note that the class `model.featureVal` includes all possible single feature values, including feature structures, alternations (<vAlt>) and complex collections (<vColl>).

19.11.4 Feature Structure Constraints

Ensuring the validity of feature structures may require much more than simply specifying the range of allowed values for each feature. There may be constraints on the co-occurrence of one feature value with the value of another feature in the same feature structure or in an embedded feature structure.

Such constraints on valid feature structures are expressed as a series of conditional and biconditional tests in the <fsConstraints> part of an <fsDecl>. A particular feature structure is valid only if it meets all the constraints. The <cond> element encodes the conventional if-then conditional of boolean logic which succeeds when both the antecedent and consequent are true, or whenever the antecedent is false. The <bicond> element encodes the biconditional (if and only if) operation of boolean logic. It succeeds only when the corresponding if-then conditionals in both directions are true. In feature structure constraints the antecedent and consequent are expressed as feature structures; they are considered true if they *subsume* (see section *19.11.3. Feature Declarations*) the feature structure in question, but in the case of consequents, this truth is asserted rather than simply tested. That is to say, a conditional is enforced by determining that the antecedent does not (and will never) subsume the given feature structure, or by determining that the antecedent does subsume the given feature structure, and then unifying the consequent with it (the result of which, if successful, will be subsumed by the consequent). In practice, the enforcement of such constraints can result in periods in which the truth of a constraint with respect to a given feature structure is simply not known; in this case, the constraint must be persistently monitored as the feature structure becomes more informative until either its truth value is determined or computation fails for some other reason.

The following elements make up the <fsConstraints> part of an FSD:

`<fsConstraints>` (feature-structure constraints) specifies constraints on the content of valid feature structures.

`<cond>` (conditional feature-structure constraint) defines a conditional feature-structure constraint; the consequent and the antecedent are specified as feature structures or feature-structure collections; the constraint is satisfied if both the antecedent and the consequent subsume a given feature structure, or if the antecedent does not.

`<bicond>` (bi-conditional feature-structure constraint) defines a biconditional feature-structure constraint; both consequent and antecedent are specified as feature structures or groups of feature structures; the constraint is satisfied if both subsume a given feature structure, or if both do not.

`<then>` separates the condition from the default in an <if>, or the antecedent and the consequent in a <cond> element.

`<iff>` (if and only if) separates the condition from the consequence in a <bicond> element.

For an example of feature structure constraints, consider the following 'feature co-occurrence restrictions' extracted from the feature system for English proposed by Gazdar, et al. (1985:246–247):

```
[FCR 1: [+INV] → [+AUX, FIN]
```

```
  FCR 7: [BAR 0] ≡ [N] & [V] & [SUBCAT]
```

```
  FCR 8: [BAR 1] → ~ [SUBCAT]]
```

The first constraint says that if a construction is inverted, it must also have an auxiliary and a finite verb form. That is,

```
<cond>
  <fs>
    <f  name="INV">
      <binary  value="true"/>
    </f>
  </fs>
  <then/>
  <fs>
    <f  name="AUX">
      <binary  value="true"/>
    </f>
    <f  name="VFORM">
      <symbol  value="FIN"/>
    </f>
  </fs>
</cond>
```

The second constraint says that if a construction has a BAR value of zero (i.e., it is a sentence), then it must have a value for the features N, V, and SUBCAT. By the same token, because it is a biconditional, if it has values for N, V, and SUBCAT, it must have BAR='0'. That is,

```
<bicond>
  <fs>
    <f  name="BAR">
      <symbol  value="0"/>
    </f>
  </fs>
  <iff/>
  <fs>
    <f  name="N">
      <binary  value="true"/>
    </f>
    <f  name="V">
      <binary  value="true"/>
    </f>
    <f  name="SUBCAT">
      <binary  value="true"/>
    </f>
  </fs>
</bicond>
```

The final constraint says that if a construction has a BAR value of 1 (i.e., it is a phrase), then the SUBCAT feature should be absent (~). This is not biconditional, since there are other instances under which the SUBCAT feature is inappropriate. That is,

```
<cond>
  <fs>
    <f  name="BAR">
      <symbol  value="1"/>
    </f>
  </fs>
  <then/>
  <fs>
    <f  name="SUBCAT">
      <binary  value="false"/>
    </f>
  </fs>
</cond>
```

Note that <cond> and <bicond> use the empty tags <then> and <iff>, respectively, to separate the antecedent and consequent. These are primarily for the sake of enhancing human readability.

19.11.5 A Complete Example

To summarize this chapter, the complete FSD for the example that has run through the chapter is reproduced below:

19.12 Formal Definition and Implementation

This elements discussed in this chapter constitute a module of the TEI scheme which is formally defined as follows:

Module iso-fs: Feature structures

- *Elements defined*: bicond binary cond default f fDecl fDescr fLib fs fsConstraints fsDecl fsDescr fsdDecl fsdLink fvLib if iff numeric string symbol then vAlt vColl vDefault vLabel vMerge vNot vRange
- *Classes defined*: model.fsdDeclPart

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema.*

20 Graphs, Networks, and Trees

Graphical representations are widely used for displaying relations among informational units because they help readers to visualize those relations and hence to understand them better. Two general types of graphical representations may be distinguished.

- *Graphs*, in the strictly mathematical sense, consist of points, often called *nodes* or *vertices*, and connections among them, called *arcs*, or under certain conditions, *edges*. Among the various types of graphs are *networks* and *trees*. Graphs generally and networks in particular are dealt with directly below. Trees are dealt with separately in sections *20.2. Trees* and *20.3. Another Tree Notation*.[120]
- *Charts*, which typically plot data in two or more dimensions, including plots with orthogonal or radial axes, bar charts, pie charts, and the like. These can be described using the elements defined in the module for figures and graphics; see chapter *15. Tables, Formulæ, Graphics, and Notated Music*.

Among the types of qualitative relations often represented by graphs are organizational hierarchies, flow charts, genealogies, semantic networks, transition networks, grammatical relations, tournament schedules, seating plans, and directions to people's houses. In developing recommendations for the encoding of graphs of various types, we have relied on their formal mathematical definitions and on the most common conventions for representing them visually. However, it must be emphasized that these recommendations do not provide for the full range of possible graphical representations, and deal only partially with questions of design, layout, and placement.

20.1 Graphs and Digraphs

Broadly speaking, graphs can be divided into two types: *undirected* and *directed*. An undirected graph is a set of *nodes* (or *vertices*) together with a set of pairs of those vertices, called *arcs* or *edges*. Each node in an arc of an undirected graph is said to be *incident* with that arc, and the two vertices (nodes) which make up an arc are said to be *adjacent*. An directed graph is like an undirected graph except that the arcs are *ordered pairs* of nodes. In the case of directed graphs, the term *edge* is not used; moreover, each arc in a directed graph is said to be *adjacent from* the node from which the arc emanates, and *adjacent to* the node to which the arc is directed. We use the element <graph> to encode graphs as a whole, <node> to encode nodes or vertices, and <arc> to encode arcs or edges; arcs can also be encoded by attributes on the <node> element. These elements have the following descriptions and attributes:

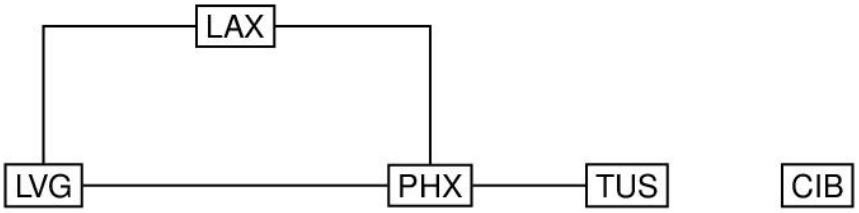
`<graph>` (graph) encodes a graph, which is a collection of nodes, and arcs which connect the nodes.

`<node>` (node) encodes a node, a possibly labeled point in a graph.

`<arc>` (arc) encodes an arc, the connection from one node to another in a graph.

Before proceeding, some additional terminology may be helpful. We define a *path* in a graph as a sequence of nodes n1, ..., nk such that there is an arc from each ni to ni+1 in the sequence. A *cyclic path*, or *cycle* is a path leading from a particular node back to itself. A graph that contains at least one cycle is said to be *cyclic*; otherwise it is *acyclic*. We say, finally, that a graph is *connected* if there is a path from some node to every other node in the graph; any graph that is not connected is said to be *disconnected*.

Here is an example of an undirected, cyclic disconnected graph, in which the nodes are annotated with three-letter codes for airports, and the arcs connecting the nodes are represented by horizontal and vertical lines, with 90 degree bends used simply to avoid having to draw diagonal lines.



Next is a markup of the graph, using <arc> elements to encode the arcs.

```
<graph  type="undirected"  xml:id="CUG1"
  order="5"  size="4">
```

[120] The treatment here is largely based on the characterizations of graph types in ?

```
  <label>Airline Connections in Southwestern USA</label>
  <node  xml:id="LAX"  degree="2">
    <label>LAX</label>
  </node>
  <node  xml:id="LVG"  degree="2">
    <label>LVG</label>
  </node>
  <node  xml:id="PHX"  degree="3">
    <label>PHX</label>
  </node>
  <node  xml:id="TUS"  degree="1">
    <label>TUS</label>
  </node>
  <node  xml:id="CIB"  degree="0">
    <label>CIB</label>
  </node>
  <arc  from="#LAX"  to="#LVG"/>
  <arc  from="#LAX"  to="#PHX"/>
  <arc  from="#LVG"  to="#PHX"/>
  <arc  from="#PHX"  to="#TUS"/>
</graph>
```

The first child element of <graph> may be a <label> to record a label for the graph; similarly, the <label> child of each <node> element records the labels of that node. The *order* and *size* attributes on the <graph> element record the number of nodes and number of arcs in the graph respectively; these values are optional (since they can be computed from the rest of the graph), but if they are supplied, they must be consistent with the rest of the encoding. They can thus be used to help check that the graph has been encoded and transmitted correctly. The *degree* attribute on the <node> elements record the number of arcs that are incident with that node. It is optional (because redundant), but can be used to help in validity checking: if a value is given, it must be consistent with the rest of the information in the graph. Finally, the *from* and *to* attributes on the <arc> elements provide pointers to the nodes connected by those arcs. Since the graph is undirected, no directionality is implied by the use of the *from* and *to* attributes; the values of these attributes could be interchanged in each arc without changing the graph.

The *adj*, *adjFrom*, and *adjTo* attributes of the <node> element provide an alternative method of representing unlabeled arcs, their values being pointers to the nodes which are adjacent to or from that node. The *adj* attribute is to be used for undirected graphs, and the *adjFrom* and *adjTo* attributes for directed graphs. It is a semantic error for the directed adjacency attributes to be used in an undirected graph, and vice versa. Here is a markup of the preceding graph, using the *adj* attribute to represent the arcs.

```
<graph  type="undirected"  xml:id="CUG2"
  order="5"  size="4">
  <label>Airline Connections in Southwestern USA</label>
  <node  xml:id="LAX2"  degree="2"
    adj="#LVG2 #PHX2">
    <label>LAX2</label>
  </node>
  <node  xml:id="LVG2"  degree="2"
    adj="#LAX2 #PHX2">
    <label>LVG2</label>
  </node>
  <node  xml:id="PHX2"  degree="3"
    adj="#LAX2 #LVG2 #TUS2">
    <label>PHX2</label>
  </node>
  <node  xml:id="TUS2"  degree="1"  adj="#PHX2">
    <label>TUS2</label>
```

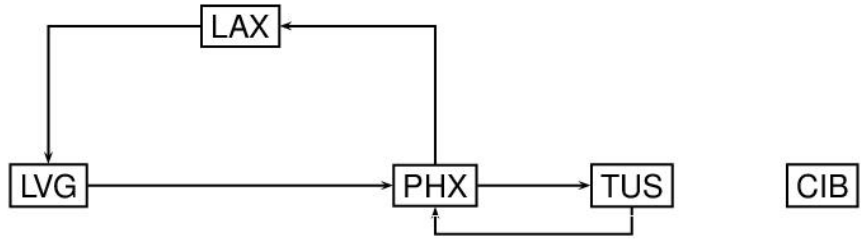
```
  </node>
  <node  xml:id="CIB2"  degree="0">
    <label>CIB2</label>
  </node>
</graph>
```

Note that each arc is represented twice in this encoding of the graph. For example, the existence of the arc from LAX to LVG can be inferred from each of the first two <node> elements in the graph. This redundancy, however, is not required: it suffices to describe an arc in any one of the three places it can be described (either adjacent node, or in a separate <arc> element). Here is a less redundant representation of the same graph.

```
<graph  type="undirected"  xml:id="CUG3"
  order="5"  size="4">
  <label>Airline Connections in Southwestern USA</label>
  <node  xml:id="LAX3"  degree="2"
    adj="#LVG3 #PHX3">
    <label>LAX3</label>
  </node>
  <node  xml:id="LVG3"  degree="2"  adj="#PHX3">
    <label>LVG3</label>
  </node>
  <node  xml:id="PHX3"  degree="3"  adj="#TUS3">
    <label>PHX3</label>
  </node>
  <node  xml:id="TUS3"  degree="1">
    <label>TUS3</label>
  </node>
  <node  xml:id="CIB3"  degree="0">
    <label>CIB3</label>
  </node>
</graph>
```

Although in many cases the <arc> element is redundant (since arcs can be described using the adjacency attributes of their adjacent nodes), it has nevertheless been included in this module, in order to allow the convenient specification of identifiers, display or rendition information, and labels for each arc (using the attributes *xml:id*, *rend*, and a child <label> element).

Next, let us modify the preceding graph by adding directionality to the arcs. Specifically, we now think of the arcs as specifying selected routes from one airport to another, as indicated by the direction of the arrowheads in the following diagram.



Here is an encoding of this graph, using the <arc> element to designate the arcs.

```
<graph  type="directed"  xml:id="RDG1"
  order="5"  size="5">
```

```
  <label>Selected Airline Routes in Southwestern USA</label>
  <node  xml:id="LAX4"  inDegree="1"
    outDegree="1">
    <label>LAX4</label>
  </node>
  <node  xml:id="LVG4"  inDegree="1"
    outDegree="1">
    <label>LVG4</label>
  </node>
  <node  xml:id="PHX4"  inDegree="2"
    outDegree="2">
    <label>PHX4</label>
  </node>
  <node  xml:id="TUS4"  inDegree="1"
    outDegree="1">
    <label>TUS4</label>
  </node>
  <node  xml:id="CIB4"  inDegree="0"
    outDegree="0">
    <label>CIB4</label>
  </node>
  <arc  from="#LAX4"  to="#LVG4"/>
  <arc  from="#LVG4"  to="#PHX4"/>
  <arc  from="#PHX4"  to="#LAX4"/>
  <arc  from="#PHX4"  to="#TUS4"/>
  <arc  from="#TUS4"  to="#PHX4"/>
</graph>
```

The attributes *inDegree* and *outDegree* indicate the number of nodes which are adjacent to and from the node concerned respectively.

Here is another encoding of the graph, using the *adjTo* and *adjFrom* attributes on nodes to designate the arcs.

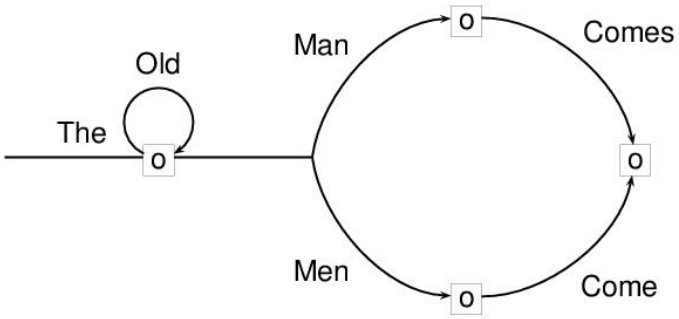
```
<graph  type="directed"  xml:id="RDG2"
  order="5"  size="5">
  <label>Selected Airline Routes in Southwestern USA</label>
  <node  xml:id="LAX5"  inDegree="1"
    outDegree="1"  adjTo="#LVG5"  adjFrom="#PHX5">
    <label>LAX5</label>
  </node>
  <node  xml:id="LVG5"  inDegree="1"
    outDegree="1"  adjFrom="#LAX5"  adjTo="#PHX5">
    <label>LVG5</label>
  </node>
  <node  xml:id="PHX5"  inDegree="2"
    outDegree="2"  adjTo="#LAX5 #TUS"  adjFrom="#LVG5 #TUS5">
    <label>PHX5</label>
  </node>
  <node  xml:id="TUS5"  inDegree="1"
    outDegree="1"  adjTo="#PHX5"  adjFrom="#PHX5">
    <label>TUS5</label>
  </node>
  <node  xml:id="CIB5"  inDegree="0"
    outDegree="0">
    <label>CIB5</label>
  </node>
</graph>
```

If we wish to label the arcs, say with flight numbers, then <arc> elements must be used to hold the <label> elements, as in the following example.

```
<graph type="directed" xml:id="RDG3"
  order="5" size="5">
  <label>Selected Airline Routes in Southwestern USA</label>
  <node xml:id="LAX6">
    <label>LAX6</label>
  </node>
  <node xml:id="LVG6">
    <label>LVG6</label>
  </node>
  <node xml:id="PHX6">
    <label>PHX6</label>
  </node>
  <node xml:id="TUS6">
    <label>TUS6</label>
  </node>
  <node xml:id="CIB6">
    <label>CIB6</label>
  </node>
  <arc from="#LAX6" to="#LVG6">
    <label>SW117</label>
  </arc>
  <arc from="#LVG6" to="#PHX6">
    <label>SW711</label>
  </arc>
  <arc from="#PHX6" to="#LAX6">
    <label>AA218</label>
  </arc>
  <arc from="#PHX6" to="#TUS6">
    <label>AW229</label>
  </arc>
  <arc from="#TUS6" to="#PHX6">
    <label>AW225</label>
  </arc>
</graph>
```

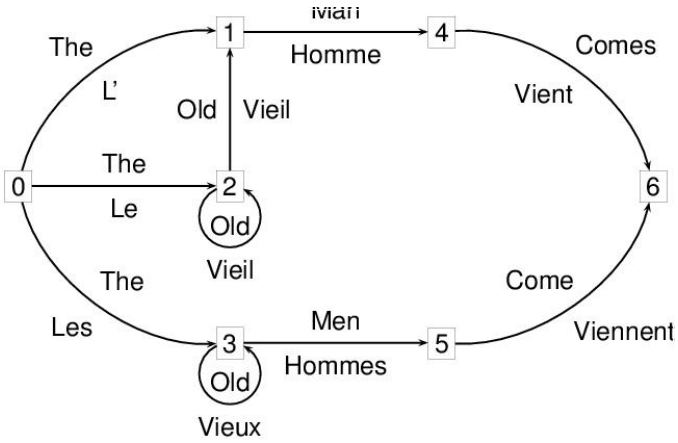
20.1.1 Transition Networks

For encoding transition networks and other kinds of directed graphs in which distinctions among types of nodes must be made, the *type* attribute is provided for <node> elements. In the following example, the *initial* and *final* nodes (or *states*) of the network are distinguished. It can be understood as accepting the set of strings obtained by traversing it from its initial node to its final node, and concatenating the labels.



```
<graph type="network-transition"
  xml:id="SS8" order="5" size="6">
  <label>(8)</label>
  <node xml:id="Q0" inDegree="0"
    outDegree="1" type="initial"/>
  <node xml:id="Q1" inDegree="2"
    outDegree="3"/>
  <node xml:id="Q2" inDegree="1"
    outDegree="1"/>
  <node xml:id="Q3" inDegree="1"
    outDegree="1"/>
  <node xml:id="Q4" inDegree="2"
    outDegree="0" type="final"/>
  <arc from="#Q0" to="#Q1">
    <label>THE</label>
  </arc>
  <arc from="#Q1" to="#Q1">
    <label>OLD</label>
  </arc>
  <arc from="#Q1" to="#Q2">
    <label>MAN</label>
  </arc>
  <arc from="#Q1" to="#Q3">
    <label>MEN</label>
  </arc>
  <arc from="#Q2" to="#Q4">
    <label>COMES</label>
  </arc>
  <arc from="#Q3" to="#Q4">
    <label>COME</label>
  </arc>
</graph>
```

A finite state transducer has two labels on each arc, and can be thought of as representing a mapping from one sequence of labels to the other. The following example represents a transducer for translating the English strings accepted by the network in the preceding example into French. The nodes have been annotated with numbers, for convenience.



```
<graph type="transducer" order="7" size="10">
  <node xml:id="T0" inDegree="0"
    outDegree="3" type="initial">
    <label>0</label>
  </node>

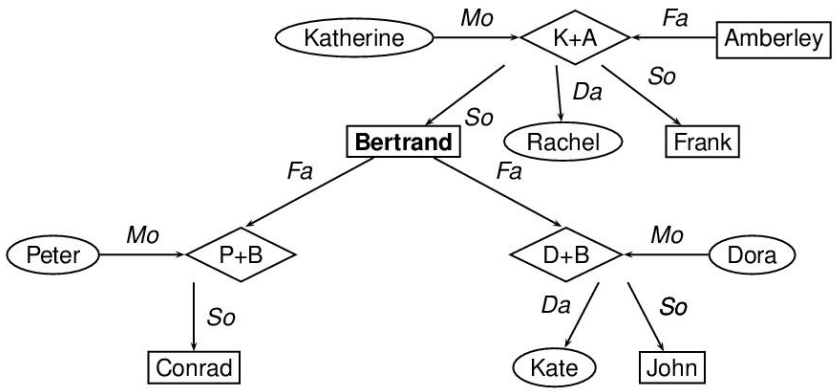
  <arc  from="#T5"  to="#T6">
    <label>COME</label>
    <label>VIENNENT</label>
  </arc>
</graph>
```

20.1.2 Family Trees

The next example provides an encoding a portion of a family tree[121] in which nodes are used to represent individuals and parents of individuals, and arcs are used to represent common parentage and descent links. Let us suppose, further, that information about individuals is contained in feature structures, which are contained in feature-structure libraries elsewhere (see *19.4. Feature Libraries and Feature-Value Libraries*). We can use the *value* attribute on <node> elements to point to those feature structures. In this particular representation of the graph, nodes representing females are framed by ovals, nodes representing males are framed by boxes, and nodes representing parents are framed by diamonds.

[121] The family tree is that of the mathematician and philosopher Bertrand Russell, whose third wife was commonly known as Peter. The information presented here is taken from Pereira and Shieber (1987).



```
<graph type="family_tree" order="13"
 size="12">

</graph>
```

20.1.3 Historical Interpretation

For our final example, we represent graphically the relationships among various geographic areas mentioned in a seventeenth-century Scottish document. The document itself is a ‘sasine’, which records a grant of land from the earl of Argyll to one Donald McNeill, and reads in part as follows (abbreviations have been expanded silently, and ‘[…]’ marks illegible passages):

> Item instrument of Sasine given the said Hector Mcneil confirmed and dated 28 May 1632 [...] at Edinburgh upon the 15 June 1632
>
> Item ane charter granted by Archibald late earl of Argyle and Donald McNeill of Gallachalzie wh makes mention that ... the said late Earl yields and grants to the said Donald MacNeill ...
>
> All and hail the two merk land of old extent of Gallachalzie with the pertinents by and in the lordship of Knapdale within the sherrifdome of Argyll
>
> [description of other lands granted follows ...]
>
> This Charter is dated at Inverary the 15th May 1669

In this example, we are concerned with the land and pertinents (i.e. accompanying sources of revenue) described as 'the two merk land of old extent of Gallachalzie with the pertinents by and in the lordship of Knapdale within the sherrifdom of Argyll'.

The passage concerns the following pieces of land:

- the Earl of Argyll's land (i.e. the lands granted by this clause of the sasine)
- two mark of land in Gallachalzie
- the pertinents for this land
- the Lordship of Knapdale
- the sherrifdom of Argyll

We will represent these geographic entities as nodes in a graph. Arcs in the graph will represent the following relationships among them:

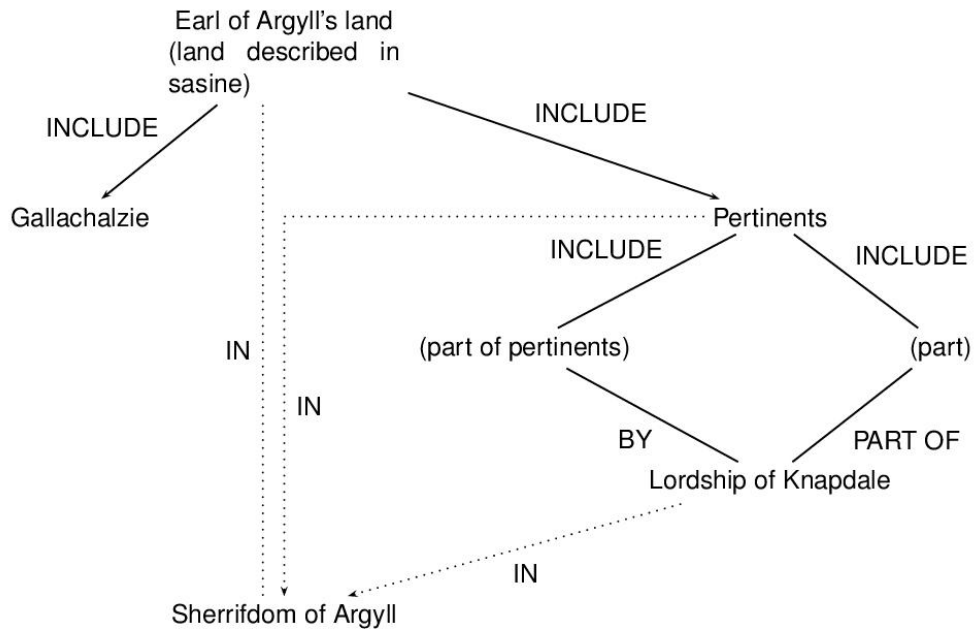
- containment (INCLUDE)
- location within (IN)
- contiguity (BY)
- constituency (PART OF)

Note that these relationships are logically related: 'include' and 'in', for example, are inverses of each other: the Earl of Argyll's land includes the parcel in Gallachalzie, and the parcel is therefore in the Earl of Argyll's land. Given an explicit set of inference rules, an appropriate application could use the graph we are constructing to infer the logical consequences of the relationships we identify.

Let us assume that feature-structure analyses are available which describe Gallachalzie, Knapdale, and Argyll. We will link to those feature structures using the *value* attribute on the nodes representing those places. However, there may be some uncertainty as to which noun phrase is modified by the phrase 'within the sheriffdome of Argyll': perhaps the entire lands (land and pertinents) are in Argyll, perhaps just the pertinents are, or perhaps only Knapdale is (together with the portion of the pertinents which is in Knapdale). We will represent all three of these interpretations in the graph; they are, however, mutually exclusive, which we represent using the *exclude* attribute defined in chapter *17. Linking, Segmentation, and Alignment.*[122]

We represent the graph and its encoding as follows, where the dotted lines in the graph indicate the mutually exclusive arcs; in the encoding, we use the *exclude* attribute to indicate those arcs.

[122] That is, the three syntactic interpretations of the clause are mutually exclusive. The notion that the pertinents are in Argyll is clearly not inconsistent with the notion that both the land in Gallachalzie and the pertinents are in Argyll. The graph given here describes the possible interpretations of the clause itself, not the sets of inferences derivable from each syntactic interpretation, for which it would be convenient to use the facilities described in chapter *19. Feature Structures.*



The graph formalizes the following relationships:

- the Earl of Argyll's land *includes* (the parcel of land in) Gallachalzie
- the Earl of Argyll's land *includes* the pertinents of that parcel
- the pertinents are (in part) *by* the Lordship of Knapdale
- the pertinents are (in part) *part of* the Lordship of Knapdale
- the Earl of Argyll's land, or the pertinents, or the Lordship of Knapdale, is *in* the Sherrifdom of Argyll

We encode the graph thus:

```
<graph type="directed" order="7" size="9">
  <node xml:id="EARL">
    <label>Earl of Argyll's land</label>
  </node>
  <node xml:id="GALL"
    value="http://example.com/people/scots#gall">

    <label>IN</label>
  </arc>
</graph>
```

20.2 Trees

A *tree* is a connected acyclic graph. That is, it is possible in a tree graph to follow a path from any vertex to any other vertex, but there are no paths that lead from any vertex to itself. A rooted tree is a directed graph based on a tree; that is, the arcs in the graph correspond to the arcs of a tree such that there is exactly one node, called the *root*, for which there is a path from that node to all other nodes in the graph. For our purposes, we may ignore all trees except for rooted trees, and hence we shall use the <tree> element for rooted trees, and the <root> element for its root. The nodes adjacent to a given node are called its *children*, and the node adjacent from a given node is called its *parent*. Nodes with both a parent and children are called *internal nodes*, for which we use the <iNode> element. A node with no children is tagged as a <leaf>. If the children of a node are ordered from left to right, then we say that that node is *ordered*. If all the nodes of a tree are ordered, then we say that the tree is an *ordered tree*. If some of the nodes of a tree are ordered and others are not, then the tree is a *partially ordered tree*. The ordering of nodes and trees may be specified by an attribute; we take the default ordering for trees to be ordered, that roots inherit their ordering from the trees in which they occur, and internal nodes inherit their ordering from their

parents. Finally, we permit a node to be specified as following other nodes, which (when its parent is ordered) it would be assumed to precede, giving rise to crossing arcs. The elements used for the encoding of trees have the following descriptions and attributes.

`<tree>` (tree) encodes a tree, which is made up of a root, internal nodes, leaves, and arcs from root to leaves.

- `@arity` gives the maximum number of children of the root and internal nodes of the tree.
- `@ord` (ordered) indicates whether or not the tree is ordered, or if it is partially ordered.
- `@order` gives the order of the tree, i.e., the number of its nodes.

`<root>` (root node) represents the root node of a tree.

- `@value` identifies the root node of the network by pointing to a feature structure or other analytic element.
- `@children` identifies the elements which are the children of the root node.
- `@ord` (ordered) indicates whether or not the root is ordered.
- `@outDegree` gives the out degree of the root, the number of its children.

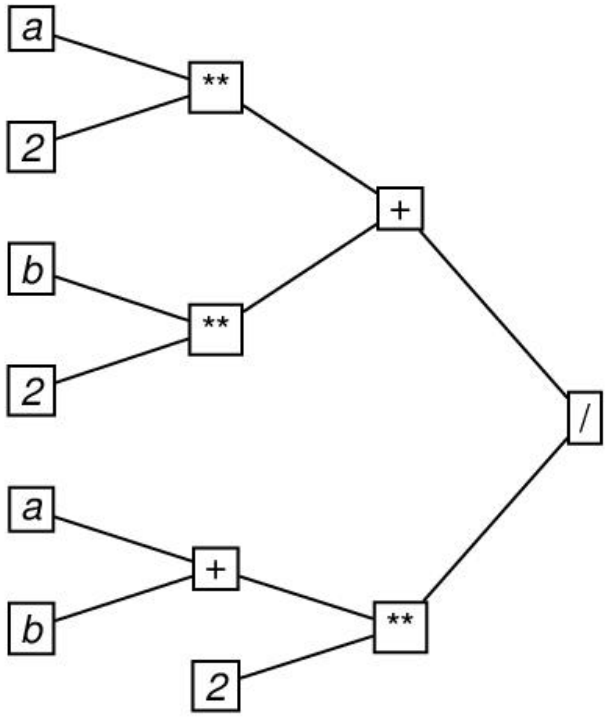
`<iNode>` (intermediate (or internal) node) represents an intermediate (or internal) node of a tree.

- `@value` indicates an intermediate node, which is a feature structure or other analytic element.
- `@children` provides a list of identifiers of the elements which are the children of the intermediate node.
- `@parent` provides the identifier of the element which is the parent of this node.
- `@ord` (ordered) indicates whether or not the internal node is ordered.
- `@follow` provides the identifier of an element which this node follows.
- `@outDegree` gives the out degree of an intermediate node, the number of its children.

`<leaf>` (leaf) encodes the leaves (terminal nodes) of a tree.

- `@value` provides a pointer to a feature structure or other analytic element.
- `@parent` provides the identifier of parent of a leaf.
- `@follow` provides an identifier of an element which this leaf follows.

Here is an example of a tree. It represents the order in which the operators of addition (symbolized by `+`), exponentiation (symbolized by `**`) and division (symbolized by `/`) are applied in evaluating the arithmetic formula `((a**2)+(b**2))/((a+b)**2)`. In drawing the graph, the root is placed on the far right, and directionality is presumed to be to the left.



```
<tree n="ex1" arity="2" ord="true" order="12">
  <root xml:id="G-DIV1"
    children="#PLU1 #EXP1">
    <label>/</label>
  </root>
  <iNode xml:id="PLU1" parent="#G-DIV1"
    children="#EXP2 #EXP3">
    <label>+</label>
  </iNode>
  <iNode xml:id="EXP1" parent="#G-DIV1"
    children="#PLU2 #NUM2.3">
    <label>**</label>
  </iNode>
  <iNode xml:id="EXP2" parent="#PLU1"
    children="#VARA1 #NUM2.1">
    <label>**</label>
  </iNode>
  <iNode xml:id="EXP3" parent="#PLU1"
    children="#VARB1 #NUM2.2">
    <label>**</label>
  </iNode>
  <iNode xml:id="PLU2" parent="#EXP1"
    children="#VARA2 #VARB2">
    <label>+</label>
  </iNode>
  <leaf xml:id="VARA1" parent="#EXP2">
    <label>a</label>
  </leaf>
  <leaf xml:id="NUM2.1" parent="#EXP2">
    <label>2</label>
  </leaf>
```

```
  <leaf  xml:id="VARB1"  parent="#EXP3">
    <label>b</label>
  </leaf>
  <leaf  xml:id="NUM2.2"  parent="#EXP3">
    <label>2</label>
  </leaf>
  <leaf  xml:id="VARA2"  parent="#PLU2">
    <label>a</label>
  </leaf>
  <leaf  xml:id="VARB2"  parent="#PLU2">
    <label>b</label>
  </leaf>
  <leaf  xml:id="NUM2.3"  parent="#EXP1">
    <label>2</label>
  </leaf>
</tree>
```

In this encoding, the *arity* attribute represents the *arity* of the tree, which is the greatest value of the *outDegree* attribute for any of the nodes in the tree. If, as in this case, *arity* is 2, we say that the tree is a *binary* tree.

Since the left-to-right (or top-to-bottom!) order of the children of the two + nodes does not affect the arithmetic result in this case, we could represent in this tree all of the arithmetically equivalent formulas involving its leaves, by specifying the attribute *ord* as false on those two <iNode> elements, the attribute *ord* as true on the <root> and other <iNode> elements, and the attribute *ord* as partial on the <tree> element, as follows.

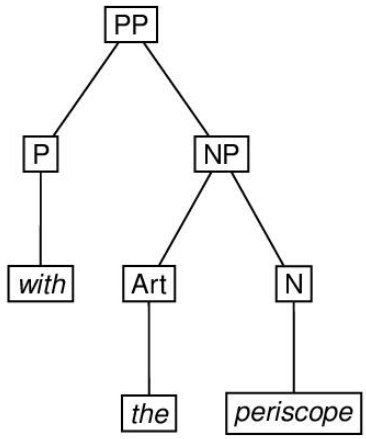
```
<tree  n="ex2"  ord="partial"  arity="2"
  order="13">
  <root  xml:id="divi1"  ord="true"
    children="#plu1 #exp1">
    <label>/</label>
  </root>
  <iNode  xml:id="plu1"  ord="false"
    parent="#divi1"  children="#exp2 #exp3">
    <label>+</label>
  </iNode>
  <iNode  xml:id="exp1"  ord="true"
    parent="#divi1"  children="#plu2 #num2.3">
    <label>**</label>
  </iNode>
  <iNode  xml:id="exp2"  ord="true"
    parent="#plu1"  children="#vara1 #num2.1">
    <label>**</label>
  </iNode>
  <iNode  xml:id="exp3"  ord="true"
    parent="#plu1"  children="#varb1 #num2.2">
    <label>**</label>
  </iNode>
  <iNode  xml:id="plu2"  ord="false"
    parent="#exp1"  children="#vara2 #varb2">
    <label>+</label>
  </iNode>
  <leaf  xml:id="vara1"  parent="#exp2">
    <label>a</label>
  </leaf>
  <leaf  xml:id="num2.1"  parent="#exp2">
    <label>2</label>
  </leaf>
```

```
  <leaf  xml:id="varb1"  parent="#exp3">
    <label>b</label>
  </leaf>
  <leaf  xml:id="num2.2"  parent="#exp3">
    <label>2</label>
  </leaf>
  <leaf  xml:id="vara2"  parent="#plu2">
    <label>a</label>
  </leaf>
  <leaf  xml:id="varb2"  parent="#plu2">
    <label>b</label>
  </leaf>
  <leaf  xml:id="num2.3"  parent="#exp1">
    <label>2</label>
  </leaf>
</tree>
```

This encoding represents all of the following:

- `((a**2)+(b**2))/((a+b)**2)`
- `((b**2)+(a**2))/((a+b)**2)`
- `((a**2)+(b**2))/((b+a)**2)`
- `((b**2)+(a**2))/((a+b)**2)`

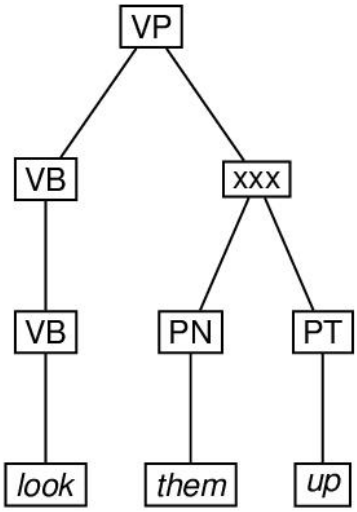
Linguistic phrase structure is very commonly represented by trees. Here is an example of phrase structure represented by an ordered tree with its root at the top, and a possible encoding.



```
<tree  n="ex3"  ord="true"  arity="2"  order="8">
  <root  xml:id="GD-PP1"
    children="#GD-P1 #GD-NP1">
    <label>PP</label>
  </root>
  <iNode  xml:id="GD-P1"  parent="#GD-PP1"
    children="#GD-WITH1">
    <label>P</label>
  </iNode>
  <leaf  xml:id="GD-WITH1"  parent="#GD-P1">
    <label>with</label>
  </leaf>
  <iNode  xml:id="GD-NP1"  parent="#GD-PP1"
```

```
    children="#GD-THE1 #GD-PERI1">
    <label>NP</label>
  </iNode>
  <iNode  xml:id="GD-ART1"  parent="#GD-NP1"
    children="#GD-THE1">
    <label>Art</label>
  </iNode>
  <leaf  xml:id="GD-THE1"  parent="#GD-ART1">
    <label>the</label>
  </leaf>
  <iNode  xml:id="GD-N1"  parent="#GD-NP1"
    children="#GD-PERI1">
    <label>N</label>
  </iNode>
  <leaf  xml:id="GD-PERI1"  parent="#GD-N1">
    <label>periscope</label>
  </leaf>
</tree>
```

Finally, here is an example of an ordered tree, in which a particular node which ordinarily would precede another is specified as following it. In the drawing, the xxx symbol indicates that the arc from VB to PT crosses the arc from VP to PN.



```
<tree  n="ex4"  arity="2"  order="8"  ord="true">
  <leaf  xml:id="GD-LOOK1"  parent="#GD-VB2">
    <label>look</label>
  </leaf>
  <leaf  xml:id="GD-THEM1"  parent="#GD-PN1">
    <label>them</label>
  </leaf>
  <leaf  xml:id="GD-UP1"  parent="#GD-PT1">
    <label>up</label>
  </leaf>
  <iNode  xml:id="GD-VB2"  parent="#GD-VB1"
    children="#GD-LOOK1">
    <label>VB</label>
  </iNode>
  <iNode  xml:id="GD-PN1"  parent="#GD-VP1"
```

```
    children="#GD-THEM1">
    <label>PN</label>
  </iNode>
  <iNode  xml:id="GD-PT1"  parent="#GD-VB1"
    children="#GD-UP1"  follow="#GD-PN1">
    <label>PT</label>
  </iNode>
  <iNode  xml:id="GD-VB1"  parent="#GD-VP1"
    children="#GD-VB2 #GD-PT1">
    <label>VB</label>
  </iNode>
  <root  xml:id="GD-VP1"
    children="#GD-VB1 #GD-PN1">
    <label>VP</label>
  </root>
</tree>
```

20.3 Another Tree Notation

In this section, we present an alternative to the method of representing the structure of ordered rooted trees given in section *20.2. Trees*, which is based on the observation that any node of such a tree can be thought of as the root of the subtree that it dominates. Thus subtrees can be thought of as the same type as the trees they are embedded in, hence the designation <eTree>, for *embedding tree*. Whereas in a <tree> the relationship among the parts is indicated by the *children* attribute, and by the names of the elements <root>, <iNode>, and <leaf>, the relationship among the parts of an <eTree> is indicated simply by the arrangement of their content. However, we have chosen to enable encoders to distinguish the terminal elements of an <eTree> by means of the empty <eLeaf> element, though its use is not required; the <eTree> element can also be used to identify the terminal nodes of <eTree> elements. We also provide a <triangle> element, which can be thought of as an underspecified <eTree>, i.e. an <eTree> in which certain information has been left out. In addition, we provide a <forest> element, which consists of one or more <tree>, <eTree>, or <triangle> elements, and a <listForest> element, which consists of one or more <forest> elements. The elements used for the encoding of embedding trees and the units containing them have the following descriptions and attributes.

`<eTree>` (embedding tree) provides an alternative to the <tree> element for representing ordered rooted tree structures.

- `@value` provides the value of an embedding tree, which is a feature structure or other analytic element.

`<triangle>` (underspecified embedding tree, so called because of its characteristic shape when drawn) provides for an underspecified <eTree>, that is, an <eTree> with information left out.

- `@value` supplies a value for the triangle, in the form of the identifier of a feature structure or other analytic element.

`<eLeaf>` (leaf or terminal node of an embedding tree) provides explicitly for a leaf of an embedding tree, which may also be encoded with the <eTree> element.

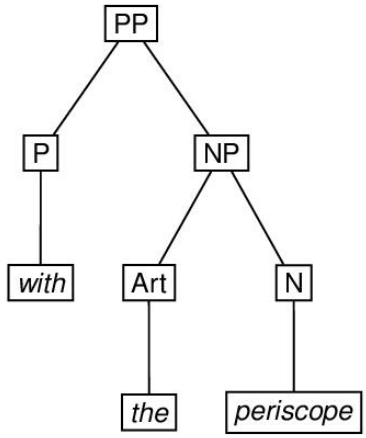
- `@value` indicates the value of an embedding leaf, which is a feature structure or other analytic element.

`<forest>` (forest) provides for groups of rooted trees.

`<listForest>` provides for lists of forests.

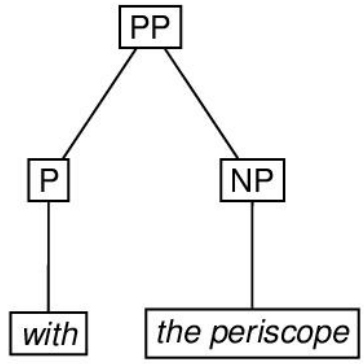
Like the <root>, <iNode>, and <leaf> of a <tree>, the <eTree>, <triangle> and <eLeaf> elements may also have *value* attributes and <label> children.

To illustrate the use of the <eTree> and <eLeaf> elements, here is an encoding of the second example in section *20.2. Trees*, repeated here for convenience.



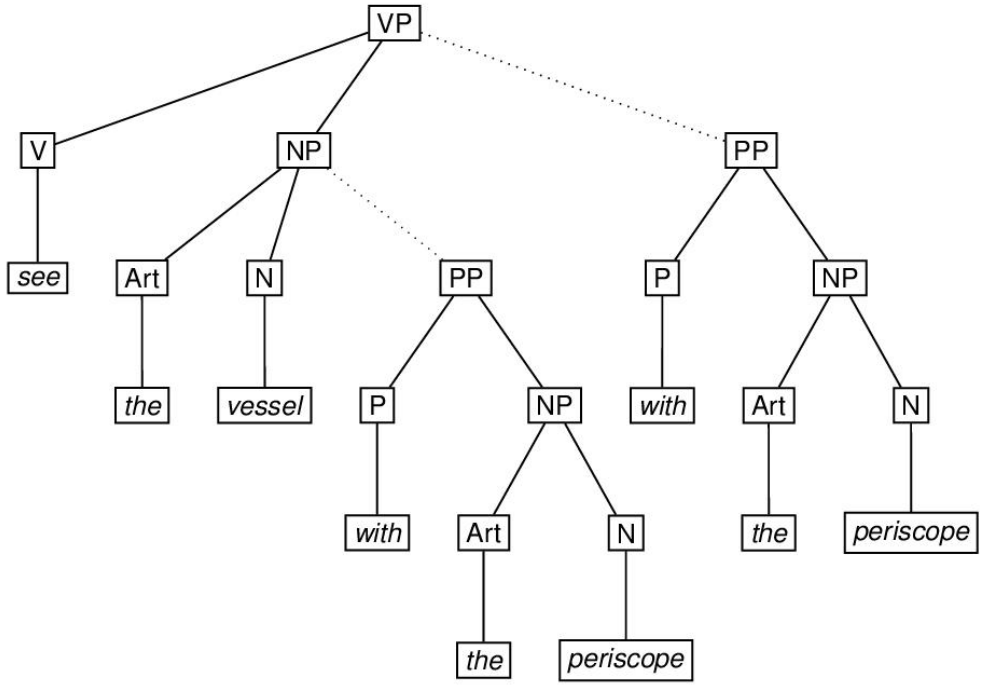
```
<eTree  n="ex1">
  <label>PP</label>
  <eTree>
    <label>P</label>
    <eLeaf>
      <label>with</label>
    </eLeaf>
  </eTree>
  <eTree>
    <label>NP</label>
    <eTree>
      <label>Art</label>
      <eLeaf>
        <label>the</label>
      </eLeaf>
    </eTree>
    <eTree>
      <label>N</label>
      <eLeaf>
        <label>periscope</label>
      </eLeaf>
    </eTree>
  </eTree>
</eTree>
```

Next, we provide an encoding, using the <triangle> element, in which the internal structure of the <eTree> labeled `NP` is omitted.



```
<eTree  n="ex2">
  <label>PP</label>
  <eTree>
    <label>P</label>
    <eLeaf>
      <label>with</label>
    </eLeaf>
  </eTree>
  <triangle>
    <label>NP</label>
    <eLeaf>
      <label>the periscope</label>
    </eLeaf>
  </triangle>
</eTree>
```

Ambiguity involving alternative tree structures associated with the same terminal sequence can be encoded relatively conveniently using a combination of the *exclude* and *copyOf* attributes described in sections *17.8. Alternation* and *17.6. Identical Elements and Virtual Copies*. In the simplest case, an <eTree> may be part of the content of exactly one of two different <eTree> elements. To mark it up, the embedded <eTree> may be fully specified within one of the embedding <eTree> elements to which it may belong, and a virtual copy, specified by the *copyOf* attribute, may appear on the other. In addition, each of the embedded elements in question is specified as excluding the other, using the *exclude* attribute. To illustrate, consider the English phrase *see the vessel with the periscope*, which may be considered to be structurally ambiguous, depending on whether the phrase *with the periscope* is a modifier of the phrase *the vessel* or a modifier of the phrase *see the vessel*. This ambiguity is indicated in the sketch of the ambiguous tree by means of the dotted-line arcs. The markup using the *copyOf* and *exclude* attributes follows the sketch.



```
<eTree  n="ex3">
  <label>VP</label>
  <eTree>
    <label>V</label>
```

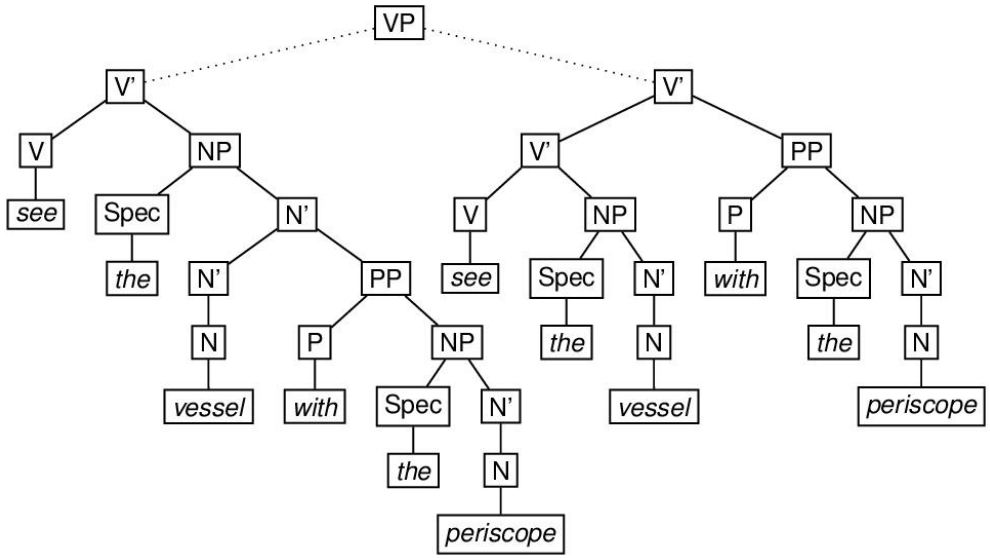
```
    <eLeaf>
      <label>see</label>
    </eLeaf>
  </eTree>
  <eTree>
    <label>NP</label>
    <eTree>
      <label>Art</label>
      <eLeaf>
        <label>the</label>
      </eLeaf>
    </eTree>
    <eTree>
      <label>N</label>
      <eLeaf>
        <label>vessel</label>
      </eLeaf>
    </eTree>
    <eTree  xml:id="GD-PPA"  exclude="#GD-PPB">
      <label>PP</label>
      <eTree>
        <label>P</label>
        <eLeaf>
          <label>with</label>
        </eLeaf>
      </eTree>
      <eTree>
        <label>NP</label>
        <eTree>
          <label>Art</label>
          <eLeaf>
            <label>the</label>
          </eLeaf>
        </eTree>
        <eTree>
          <label>N</label>
          <eLeaf>
            <label>periscope</label>
          </eLeaf>
        </eTree>
      </eTree>
    </eTree>
  </eTree>
  <eTree  xml:id="GD-PPB"  copyOf="#GD-PPA"
    exclude="#GD-PPA">
    <label>PP</label>
  </eTree>
</eTree>
```

To indicate that one of the alternatives is selected, one may specify the *select* attribute on the highest <eTree> as either #GD-PPA or #GD-PPB; see section *17.8. Alternation*.

Depending on the grammar one uses to associate structures with examples like *see the man with the periscope*, the representations may be more complicated than this. For example, adopting a version of the *X-bar* theory of phrase structure originated by Jackendoff,[123] the attachment of a modifier may require the creation of an intermediate node

[123] ?

which is not required when the attachment is not made, as shown in the following diagram. A possible encoding of this ambiguous structure immediately follows the diagram.

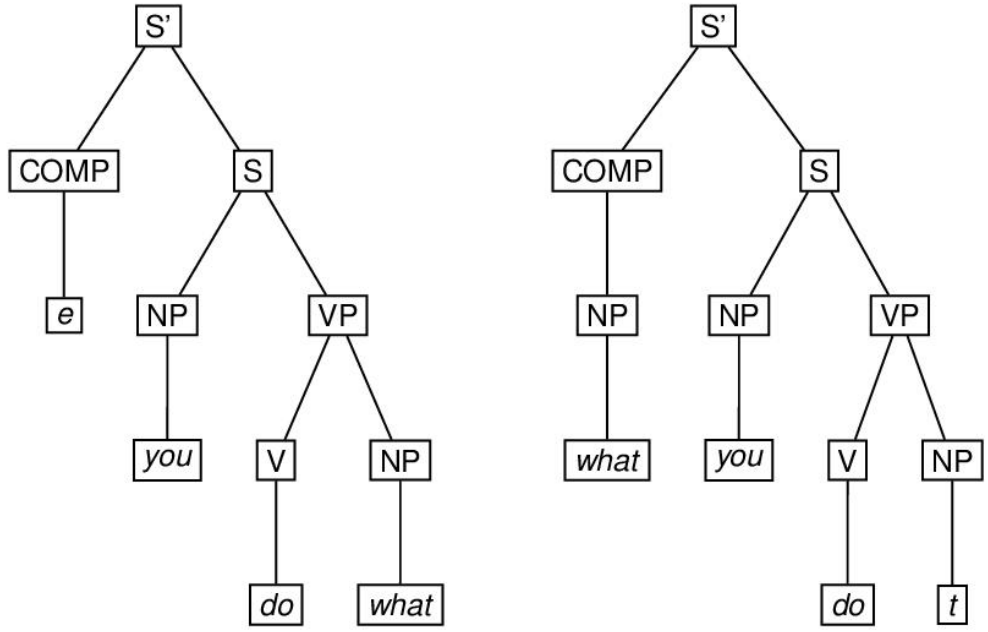


```
<eTree n="ex4">
  <label>VP</label>
  <eTree xml:id="VBARA" exclude="#VBARB">
    <label>V'</label>
    <eTree xml:id="VA">
      <label>V</label>
      <eLeaf>
        <label>see</label>
      </eLeaf>
    </eTree>
    <eTree>
      <label>NP</label>
      <eTree xml:id="SPEC1A">
        <label>Spec</label>
        <eLeaf>
          <label>the</label>
        </eLeaf>
      </eTree>
      <eTree>
        <label>N'</label>
        <eTree xml:id="NBAR2A">
          <label>N'</label>
          <eTree>
            <label>N</label>
            <eLeaf>
              <label>vessel</label>
            </eLeaf>
          </eTree>
        </eTree>
        <eTree xml:id="PPA1">
          <label>PP</label>
          <eTree>
            <label>P</label>
            <eLeaf>
              <label>with</label>
```

```
          </eLeaf>
        </eTree>
        <eTree>
          <label>NP</label>
          <eTree>
            <label>Spec</label>
            <eLeaf>
              <label>the</label>
            </eLeaf>
          </eTree>
          <eTree>
            <label>N'</label>
            <eTree>
              <label>N</label>
              <eLeaf>
                <label>periscope</label>
              </eLeaf>
            </eTree>
          </eTree>
        </eTree>
      </eTree>
    </eTree>
  </eTree>
  <eTree xml:id="VBARB" exclude="#VBARA">
    <label>V'</label>
    <eTree>
      <label>V'</label>
      <eTree xml:id="VB" copyOf="#VA">
        <label>V</label>
      </eTree>
      <eTree>
        <label>NP</label>
        <eTree xml:id="SPEC1B" copyOf="#SPEC1A">
          <label>Spec</label>
        </eTree>
        <eTree xml:id="NBAR2B" copyOf="#NBAR2A">
          <label>N'</label>
        </eTree>
      </eTree>
    </eTree>
    <eTree xml:id="PPB" copyOf="#PPA1">
      <label>PP</label>
    </eTree>
  </eTree>
</eTree>
```

A *derivation* in a generative grammar is often thought of as a set of trees. To encode such a derivation, one may use the <forest> element, in which the trees may be marked up using the <tree>, the <eTree>, or the <triangle> element. The *type* attribute may be used to specify what kind of derivation it is. Here is an example of a two-tree forest, involving application of the 'wh-movement' transformation in the derivation of *what you do* (as in *this is what you do*) from the underlying *you do what*.[124]

[124]The symbols `e` and `t` denote special theoretical constructs (*empty category* and *trace* respectively), which need not concern us here.



```
<forest  n="ex5"  type="derivation-syntactic">
  <eTree  n="Stage 1"  xml:id="S1SBAR">
    <label>S'</label>
    <eTree  xml:id="S1COMP">
      <label>COMP</label>
      <eLeaf  xml:id="S1E">
        <label>e</label>
      </eLeaf>
    </eTree>
    <eTree  xml:id="S1S">
      <label>S</label>
      <eTree  xml:id="S1NP1">
        <label>NP</label>
        <eLeaf>
          <label>you</label>
        </eLeaf>
      </eTree>
      <eTree  xml:id="S1VP">
        <label>VP</label>
        <eTree  xml:id="S1V">
          <label>V</label>
          <eLeaf>
            <label>do</label>
          </eLeaf>
        </eTree>
        <eTree  xml:id="S1NP2">
          <label>NP</label>
          <eLeaf  xml:id="S1WH">
            <label>what</label>
          </eLeaf>
        </eTree>
      </eTree>
    </eTree>
  </eTree>
  <eTree  n="Stage 2"  xml:id="S2SBAR"
```

```
    corresp="#S1SBAR">
    <label>S'</label>
    <eTree xml:id="S2COMP" corresp="#S1COMP">
      <label>COMP</label>
      <eTree copyOf="#S1NP2" corresp="#S1E">
        <label>NP</label>
      </eTree>
    </eTree>
    <eTree xml:id="S2S" corresp="#S1S">
      <label>S</label>
      <eTree xml:id="S2NP1" copyOf="#S1NP1">
        <label>NP</label>
      </eTree>
      <eTree xml:id="S2VP" corresp="#S1VP">
        <label>VP</label>
        <eTree xml:id="S2V" copyOf="#S1V">
          <label>V</label>
        </eTree>
        <eTree xml:id="S2NP2" corresp="#S1NP2">
          <label>NP</label>
          <eLeaf corresp="#S1WH">
            <label>t</label>
          </eLeaf>
        </eTree>
      </eTree>
    </eTree>
  </eTree>
</forest>
```

In this markup, we have used *copyOf* attributes to provide virtual copies of elements in the tree representing the second stage of the derivation that also occur in the first stage, and the *corresp* attribute (see section *17.5. Correspondence and Alignment*) to link those elements in the second stage with corresponding elements in the first stage that are not copies of them.

If a group of forests (e.g. a full grammatical derivation including syntactic, semantic, and phonological subderivations) is to be articulated, the grouping element <listForest> may be used.

20.4 Representing Textual Transmission

A *stemma codicum* (sometimes called just *stemma*) is a tree-like graphic structure that has become traditional in manuscript studies for representing textual transmission. Consider the following hypothetical stemma:

The nodes in this stemma represent manuscripts; each has a label (a letter) which identifies it and also distinguishes whether the manuscript is extant, lost, or hypothetical. Extant manuscripts are identified by uppercase Latin letters or words beginning with uppercase Latin letters, e.g., L, shown as aqua in this example; manuscripts no longer existing, but providing readings which are attested e.g. by note or copy made before their disappearance, are identified by lowercase Latin letters, e.g., t, shown as magenta in this example; hypothetical stages in the textual transmission, which do not necessarily correspond to real manuscripts, are given lowercase Greek letters, e.g., α and shown as gold in this example. The stemma shown above thus suggests that (on the basis of similarities in the readings of the extant and lost manuscripts) L and t share textual material that is not shared with other manuscripts (represented in this case by δ) even though no physical manuscript attesting this stage in the textual transmission has ever been identified.

Manuscripts are copied from other manuscripts. The preceding stemma represents the hypothesis that all manuscripts go back to a common ancestor (α), that the tradition split after that stage into two (β and γ), etc. Descent by copying is indicated with a solid line. According to this model, α is the earliest common hypothetical stage that can be reconstructed, and all nodes below α have a single parent, that is, were copied from a single other stage in the tradition.

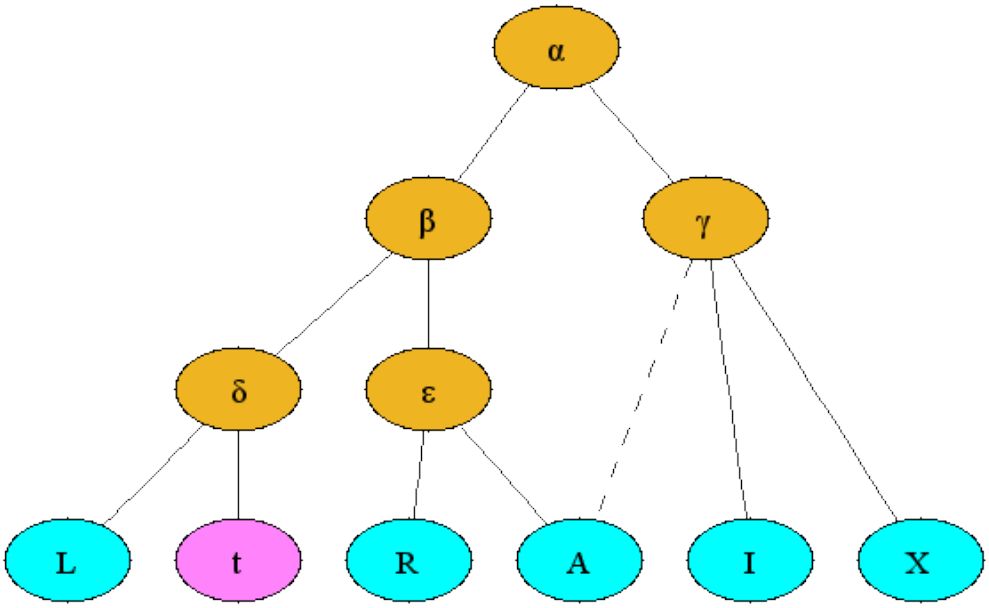


Figure 34: Example stemma

This familiar tree model is complicated because manuscripts sometimes show the influence of more than one ancestor. They may have been produced by a scribe who checked the text in one manuscript of the same work whilst copying from another, or perhaps made changes from his memory of a slightly different version of the text that he had read elsewhere. Alternatively, perhaps scribe A copied a manuscript from one source, scribe B made changes in it in the margins or between the lines (either by consulting another source directly or from memory), and another scribe then copied that manuscript, incorporating the changes into the body. Whatever the specific scenario, it is not uncommon for a manuscript to be based primarily on one source, but to incorporate features of another branch of the tradition. This mixed result is called *contamination*, and it is reflected in a stemma by a dotted line. Thus, the example above asserts that A is copied within the ε tradition, but is also contaminated from the γ tradition.

The utility of a stemma as a visualization tool is inversely proportional to the degree of contamination in the manuscript tradition. A tradition completely without contamination (called a *closed tradition*) yields a classic tree, easily represented graphically by a stemma. An *open tradition*, with substantial contamination, yields a spaghetti-like stemma characterized by crossing dotted lines, which is both difficult to read and not very informative.

The <eTree> element introduced in this chapter can be used to represent a closed tradition in a straightforward manner. Each non-terminal node is represented by a typed <eTree> element and each terminal node by an <eLeaf>. A <label> element provides a way of identifying each node, complementary to the global attributes *n* and *xml:id* attributes. For example, the closed part of the tradition headed by the label δ may be encoded as follows:

```
<eTree type="hypothetical">
  <label>δ</label>
  <eLeaf type="extant">
    <label>L</label>
  </eLeaf>
  <eLeaf type="lost">
    <label>t</label>
  </eLeaf>
</eTree>
```

To complete this representation, we need to show that the node labelled A is not derived solely from its parent node (labelled ε) but also demonstrates contamination from the node labelled γ. The easiest way to accomplish this is to include an appropriately-typed <ptr> element within the node in question, the *target* of which points to the

node labelled γ. This requires that this latter node be supplied with a value for its *xml:id* attribute. The complete representation is thus:

```
<eTree type="hypothetical">
  <label>α</label>
  <eTree type="hypothetical">
    <label>β</label>
    <eTree type="hypothetical">
      <label>δ</label>
      <eLeaf type="extant">
        <label>L</label>
      </eLeaf>
      <eLeaf type="lost">
        <label>t</label>
      </eLeaf>
    </eTree>
    <eTree type="hypothetical">
      <label>ε</label>
      <eLeaf type="extant">
        <label>R</label>
      </eLeaf>
      <eLeaf type="extant">
        <label>A</label>
        <ptr type="contamination"
          target="#gamma"/>
      </eLeaf>
    </eTree>
  </eTree>
  <eTree xml:id="gamma" type="hypothetical">
    <label>γ</label>
    <eLeaf type="extant">
      <label>I</label>
    </eLeaf>
    <eLeaf type="extant">
      <label>X</label>
    </eLeaf>
  </eTree>
</eTree>
```

In any substantial codicological project, it is likely that significantly more data will be required about the individual witnesses than indicated in the simple structures above. These Guidelines provide a rich variety of additional elements for representing such information: see in particular chapters *11. Manuscript Description*, *12. Representation of Primary Sources*, and *13. Critical Apparatus*.

20.5 Module for Graphs, Networks, and Trees

The module described in this chapter makes available the following components:

Module nets: Graphs, networks, and trees

- *Elements defined*: arc eLeaf eTree forest graph iNode leaf listForest node root tree triangle

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

21 Non-hierarchical Structures

XML employs a strongly hierarchical document model. At various points, these Guidelines discuss problems that arise when using XML to encode textual features that either do not naturally lend themselves to representation in a strictly hierarchical form or conflict with other hierarchies represented in the markup. Examples of such situations include:

- Conflict between the hierarchy established by the physical structure of a document (e.g., volume, page, column, line) and its rhetorical or linguistic structure (e.g., chapters, paragraphs, sentences, acts, scenes, etc.)
- Conflict between a verse text's metrical structure (e.g., its arrangement in stanzas and metrical lines) and its rhetorical or linguistic structure (e.g., phrases, sentences, and, for plays, acts, scenes, and speeches).
- Conflict between metrical, rhetorical, or linguistic structure and the representation of direct speech, especially if the quoted speech is interrupted by other elements (e.g., 'What', she asked, 'was that all about') or crosses metrical, rhetorical, or linguistic boundaries.
- Conflict between different analytical views or descriptions of a text or document, e.g., markup intended to encode diplomatic information about a word's appearance in a manuscript with markup intended to describe its morphology or pronunciation.

Non-nesting information poses fundamental problems for any XML-based encoding scheme, and it must be stated at the outset that no current solution combines all the desirable attributes of formal simplicity, capacity to represent all occurring or imaginable kinds of structures, suitability for formal or mechanical validation. The representation of non-hierarchical information is thus necessarily a matter of trade-offs among various sets of advantages and disadvantages.

These Guidelines support several methods for handling non-hierarchical information:

- redundant encoding of information in multiple forms (discussed in *21.1. Multiple Encodings of the Same Information*)
- the use of empty elements to delimit the boundaries of a non-nesting structure (discussed in *21.2. Boundary Marking with Empty Elements*)
- the division of a logically single non-nesting element into segments that nest properly in their immediate hierarchical context but can also be reconstituted virtually across these hierarchical boundaries (discussed *21.3. Fragmentation and Reconstitution of Virtual Elements*)
- stand-off markup: the annotation of information by pointing at it, rather than by placing XML tags within it (discussed in *21.4. Stand-off Markup*)

Some of these methods can be used in TEI-conformant documents. Others require extension.

In the sections which follow these techniques are described and their advantages and disadvantages are briefly discussed. The various solutions to the problem will be exemplified using extracts from two poems. The first is the opening quatrain from William Wordsworth's 'Scorn not the sonnet':

> Scorn not the sonnet; critic, you have frowned,
> Mindless of its just honours; with this key
> Shakespeare unlocked his heart; the melody
>
> Of this small lute gave ease to Petrarch's wound.

The second example is the third stanza from the fourth section of Robert Pinsky's 'Essay on Psychiatrists':

> Catholic woman of twenty-seven with five children
> And a first-rate body—pointed her finger
> at the back of one certain man and asked me,
> "Is that guy a psychiatrist?" and by god he was! "Yes,"
> She said, "He *looks* like a psychiatrist."
>
> Grown quiet, I looked at his pink back, and thought.

These two texts can be analysed in various ways. The first, which we might describe as the 'Metrical View', encodes the text according to its metrical features: line divisions (as here), stanzas or cantos in larger poems, and perhaps

prosodic features like stress or syllable patterns, alliteration, or rhyme. A second view, which we might describe as the 'Grammatical', encodes linguistic and rhetorical features: phonemes, morphemes, words, phrases, clauses, and sentences. A third view, the 'Dialogic', might concentrate on narrative voice: distinguishing between the narrator and their interlocutors and identifying individual segments as direct quotations. In our examples, we will restrict ourselves to relatively simple conflicts: for the *Metrical View* we will encode only metrical lines and line groups; for the *Grammatical View* we will restrict ourselves to encoding sentences; and for the *Dialogic View*, we only will distinguish direct quotation from other narration.

21.1 Multiple Encodings of the Same Information

Conceptually, the simplest method of disentangling two (or more) conflicting hierarchical views of the same information is to encode it twice (or more), each time capturing a single view.

Thus, for example, the *Metrical View* of 'Scorn not the sonnet' might be encoded as follows, using the <l> element to encode each metrical line:

```
<l>Scorn not the sonnet; critic, you have frowned,</l>
<l>Mindless of its just honours; with this key</l>
<l>Shakespeare unlocked his heart; the melody</l>
<l>Of this small lute gave ease to Petrarch's wound.</l>
```

The *Grammatical View* would be encoded by taking the same text and replacing the metrical markup with information about its sentence structure:

```
<p>
  <seg>Scorn not the sonnet;</seg>
  <seg>critic, you have frowned, Mindless of its just honours;</seg>
  <seg>with this key Shakespeare unlocked his heart;</seg>
  <seg>the melody Of this small lute gave ease to Petrarch's wound.</seg>
</p>
```

Likewise, the more complex passage from Pinsky could be encoded in three different ways to reflect the different metrical, grammatical, and dialogic views of its text:

```
<lg>
  <l>Catholic woman of twenty-seven with five children</l>
  <l>And a first-rate body—pointed her finger</l>
  <l>at the back of one certain man and asked me,</l>
  <l>"Is that guy a psychiatrist?" and by god he was! "Yes,"</l>
  <l>She said, "He <emph>looks</emph> like a psychiatrist."</l>
  <l>Grown quiet, I looked at his pink back, and thought.</l>
</lg>
```

```
<p>
  <seg>Catholic woman of twenty-seven with five children And a
     first-rate body—pointed her finger at the back of one certain man and
     asked me, "Is that guy a psychiatrist?" and by god he was!</seg>
</p>
<p>
  <seg>"Yes," She said, "He <emph>looks</emph> like a
     psychiatrist."</seg>
</p>
<p>
  <seg>Grown quiet, I looked at his pink back, and thought.</seg>
</p>
```

```
<ab>Catholic woman of twenty-seven with five children And a first-rate
body—pointed her finger at the back of one certain man and asked me,
<said>Is that guy a psychiatrist?</said> and by god he was!
<said>Yes,</said> She said, <said>He <emph>looks</emph> like a
    psychiatrist.</said> Grown quiet, I looked at his pink back, and
thought.</ab>
```

This method is TEI-conformant. Its advantages are that each way of looking at the information is explicitly represented in the data and that the individual views are simple to process. The disadvantages are that the method requires the maintenance of multiple copies of identical textual content (an invitation to inconsistency) and that there is no explicit indication that the various views, which might be in separate files, are related to each other: it might prove difficult to combine the views or access information from one view while processing the file that contains the encoding of another.[125]

21.2 Boundary Marking with Empty Elements

A second method for accommodating non-hierarchical objects in an XML document involves marking the start and end points of the non-nesting material. This prevents textual features that fall outside the privileged hierarchy from invalidating the document while identifying their beginnings and ends for further processing. The disadvantage of this method is that no single XML element represents the non-nesting material and, as a result, processing with XML technologies is significantly more difficult.

The empty elements used at each end are called *segment-boundary elements* or *segment-boundary delimiters*. There are several variations on this method of encoding.

For some common structural features, the TEI provides milestone elements that can be used to mark the beginning of a textual feature. These include <lb>, <pb>, <cb>, <handShift>, and the generic <milestone>. Using <lb>, for example, it is possible to indicate both the physical lineation of a poem on the page and its grammatical division into sentences:

```
<p>
  <seg>
    <lb  n="1"/>Scorn not the sonnet;</seg>; <seg>critic, you have
     frowned, <lb  n="2"/>Mindless of its just honours;</seg>
  <seg>with this
     key <lb  n="3"/>Shakespeare unlocked his heart;</seg>
  <seg>the melody
  <lb  n="4"/>Of this small lute gave ease to Petrarch's
     wound.</seg>
</p>
```

The use of these elements is by definition TEI-conformant. Care should be taken, however, that the meaning of the milestone elements is preserved: semantically, for example, <lb> is used to mark the start of a new (typographical) line. While in much modern poetry, typographical and metrical line divisions correspond, <lb> does not itself make a metrical claim: in encoding verse from sources, such as Old English manuscripts, where physical line beginnings are not used to indicate metrical lineation, the correspondence would break down entirely.

The segment boundaries also may be delimited by the generic <anchor> element. Attributes can then be used to indicate the type of feature being delimited and whether a given instance opens or closes the feature.

```
<l>
  <anchor  subtype="sentenceStart"
    type="delimiter"/>
```

[125] It has been shown, however, that it is possible to relate the different annotations in an indirect way: if the textual content of the annotations is identical, the very text can serve as a means for linking the different annotations, as described in ?.

```
Scorn not the sonnet;
<anchor  subtype="sentenceEnd"
   type="delimiter"/>
  <anchor  subtype="sentenceStart"
   type="delimiter"/> critic, you have frowned,
</l>
<l>Mindless of its just honours; <anchor  subtype="sentenceEnd"
   type="delimiter"/>
  <anchor  subtype="sentenceStart"
   type="delimiter"/> with this key</l>
<l>Shakespeare unlocked his heart; <anchor  subtype="sentenceEnd"
   type="delimiter"/>
  <anchor  subtype="sentenceStart"
   type="delimiter"/> the melody</l>
<l>Of this small lute gave ease to Petrarch's wound. <anchor  subtype="sentenceEnd"
   type="delimiter"/>
</l>
```

This method is TEI-conformant.

Another approach is to design custom elements that provide richer information about the feature being delimited or its boundaries. This information can be included as attribute values or as part of the element name itself: e.g., <boundaryStart element="sentence"/>… <boundaryEnd element="sentence"/>, <sentenceBoundary position="start"/>… <sentenceBoundary position="end"/>, or <sentenceBoundaryStart/>… <sentenceBoundaryEnd/>:

```
<l
   xmlns:n="http://www.example.org/ns/nonTEI">
  <n:sentenceBoundaryStart/>Scorn not the sonnet;
<n:sentenceBoundaryEnd/>
  <n:sentenceBoundaryStart/>critic, you have frowned,
</l>
<l>Mindless of its just honours; <n:sentenceBoundaryEnd/>
  <n:sentenceBoundaryStart/>with this key</l>
<l>Shakespeare unlocked his heart; <n:sentenceBoundaryEnd/>
  <n:sentenceBoundaryStart/>the melody</l>
<l>Of this small lute gave ease to Petrarch's wound. <n:sentenceBoundaryEnd/>
</l>
```

If the custom elements can be replaced by TEI elements and attributes without loss of information, this method is TEI-conformant (see *24.4. Conformance*); if the custom elements introduce information or distinctions that cannot be captured using standard TEI elements, the method is an extension.

Finally, elements that are normally used to encode nesting textual features (e.g., <said>, <seg>, <l>, etc.) can be adapted so that they serve as empty segment boundary delimiters when the features they encode cross-hierarchical boundaries. Additional attributes (*sID* and *eID* in the example below) are added to these elements in order to allow the unambiguous correlation of start and end points. This method has been introduced in the markup literature under various names, including Trojan milestones, HORSE markup, CLIX, and COLT. It is described in detail by ?):

```
<lg
   xmlns:hr="http://www.example.org/ns/nonTEI">
  <l>
   <seg>Scorn not the sonnet;</seg>
   <hr:s  sID="s02"/>critic, you have frowned, </l>
  <l>Mindless of its just honours; <hr:s  eID="s02"/>
   <hr:s  sID="s03"/>with this key </l>
```

```
  <l>Shakespeare unlocked his heart; <hr:s  eID="s03"/>
    <hr:s  sID="s04"/>the melody </l>
  <l>Of this small lute gave ease to Petrarch's wound. <hr:s  eID="s04"/>
  </l>
</lg>
```

Depending on how the modifications are carried out, this method may be TEI-conformant, may represent an extension of the TEI, or may produce a non-conformant document.

- The method is TEI-conformant if the modified elements and attributes can be mapped without loss of information to existing TEI markup structures such as milestone or anchor elements automatically (see *24.4. Conformance*).
- The method represents an Extension if the modified elements are placed in a distinct, non-TEI namespace (see *24.4. Conformance*).
- The method is non-conformant—and indeed strongly deprecated—if the modified elements and attributes are not placed in a distinct, non-TEI namespace (see *24.4.3. Conformance to the TEI Abstract Model*).

In each of the above examples (except the last), the relationship between the start and end delimiters (where these exist) of a given feature is implicit: it is assumed that ”end” delimiters close the nearest preceding ”start” delimiter, or, in the case of milestones, that the milestone marks both the end of the preceding example and the beginning of the next. Complications arise, however, when the non-nesting text overlaps with other non-nesting text of the same type, as, for example, in a grammatical analysis of the various possible interpretations of the noun phrase *fast trains and planes*. In this case, the adjective *fast* can be understood as either modifying *trains and planes* or just *trains*:

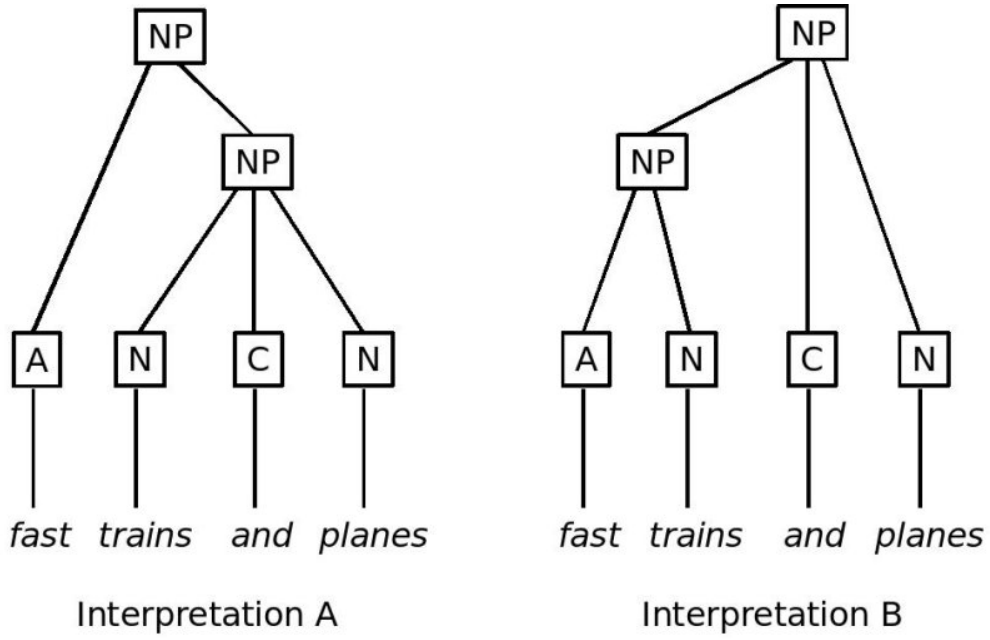

Figure 35: Two interpretations of the phrase *Fast trains and planes*

In order to encode the possible analyses of this phrase, an unambiguous method of associating opening and closing segment boundary delimiters is required:

```
<phr  function="NP">
  <anchor  type="delimiter"  subtype="NPstart"
    xml:id="NPInterpretationB"/>
  <w  function="A">Fast</w>
```

```
  <anchor  type="delimiter"  subtype="NPstart"
    xml:id="NPInterpretationA"/>
  <w  function="N">trains</w>
  <anchor  type="delimiter"  subtype="NPend"
    corresp="#NPInterpretationB"/>
  <w  function="C">and</w>
  <w  function="N">planes</w>
  <anchor  type="delimiter"  subtype="NPend"
    corresp="#NPInterpretationA"/>
</phr>
```

In this encoding, the first interpretation, in which *fast* modifies the NP *trains and planes*, the NP *trains and planes* is opened using an <anchor> tag with the *xml:id* value *NPInterpretationA* and closed with an <anchor> with the same value on *corresp*; in the second interpretation, in which *fast* forms a NP with *trains*, the NP *fast cars* is opened using an <anchor> tag with the *xml:id* value *NPInterpretationB* and closed with an <anchor> tag that has the same value on *corresp*.

Despite their advantages, segment boundary delimiters incur the disadvantage of cumbersome processing: since the elements of the analysis (e.g., the sentences in the poems, or phrases in the above example) are not uniformly represented by nodes in the document tree, they must be reconstituted by software in an ad hoc fashion, which is likely to be difficult and may be error prone.

Most important for some encoders, the method also disguises the relationship between the beginning and the ending of each logical element. This makes it impossible for standard validation software to provide the same kind of validation possible elsewhere in the encoding. When using grammar-based schema languages it is not possible to define a content model for the range limited by empty elements.[126]

21.3 Fragmentation and Reconstitution of Virtual Elements

A third method involves breaking what might be considered a single logical (but non-nesting) element into multiple smaller structural elements that fit within the dominant hierarchy but can be reconstituted virtually. For example, if a passage of direct discourse begins in the middle of one paragraph and continues for several more paragraphs, one could encode the passage as a series of <said> elements, each fitting within a <p> element. The resulting encoding is valid XML, but the text in each <said> element represents only a portion of the complete passage of direct discourse. For this reason these elements are sometimes called 'partial elements'.

In the case of our selection from Pinsky's poem, for example, the second passage of direct quotation, which crosses a line boundary and is broken up by a *She said* in the narrator's voice, can be made to fit within the hierarchy established by the metrical lineation by using two <said> elements:

```
<lg>
  <l>Catholic woman of twenty-seven with five children</l>
  <l>And a first-rate body—pointed her finger</l>
  <l>at the back of one certain man and asked me,</l>
  <l>
    <said  n="quotation1">Is that guy a psychiatrist?</said> and by god he was!
  <said  n="quotation2">Yes,</said>
  </l>
  <l>She said, <said  n="quotation2">He <emph>looks</emph> like a
        psychiatrist.</said>
  </l>
  <l>Grown quiet, I looked at his pink back, and thought.</l>
</lg>
```

[126] Grammar based schema languages (e.g., DTD, W3C Schema, and RELAX NG) are used to define markup languages (e.g., XHTML or TEI). Rule-based schema languages (e.g., Schematron) can be used to define further constraints. Such a rule-based schema language permits a sequence of certain elements between empty elements to be legitimized or prohibited.

Similarly, the sentences in our example from Wordsworth could be encoded:

```
<l>
  <seg  n="sentence1">Scorn not the sonnet;</seg>
  <seg  n="sentence2">critic, you have frowned,</seg>
</l>
<l>
  <seg  n="sentence2">Mindless of its just honours;</seg>
  <seg  n="sentence3">with this key</seg>
</l>
<l>
  <seg  n="sentence3">Shakespeare unlocked his heart;</seg>
  <seg  n="sentence4">the melody</seg>
</l>
<l>
  <seg  n="sentence4">Of this small lute gave ease to Petrarch's wound.</seg>
</l>
```

There are two main problems with this type of encoding. The first is that it invariably means that the encoding will have more elements claiming to represent a feature than there are actual instances of that feature in the text. Thus, for example, the passage from 'Scorn not the sonnet' marks seven spans of text using <seg>, even though there are only four linguistic sentences in the passage.

The second problem is that it can be semantically misleading. Although they are tagged using the element for *sentence*, for example, very few of the textual features encoded using <seg> in this example represent actual linguistic sentences: *with this key*, for example, is a prepositional phrase, not a sentence; *Of this small lute gave ease to Petrarch's wound* is a string corresponding to no single grammatical category.

Taken together, these problems can make automatic analysis of the fragmented features difficult. An analysis that intended to count the number of sentences in Wordsworth's poem, for example, would arrive at an inflated figure if it understood the <seg> elements to represent complete rhetorical sentences; if it wanted to do an analysis of his syntax, it would not be able to assume that <seg> delimited linguistic sentences.

The technique of fragmentation is often complemented by the technique of virtual joins. Virtual joins may be used to combine objects in the text to a new hierarchy. Here is 'Scorn not the sonnet' again; this time the relationship between the parts of the fragmented sentences is indicated explicitly using the *next* and *prev* attributes described in *17.7. Aggregation*.

```
<l>
  <seg>Scorn not the sonnet;</seg>
  <seg  next="#s2b"  xml:id="s2a">critic, you have frowned,</seg>
</l>
<l>
  <seg  prev="#s2a"  xml:id="s2b">Mindless of its just honours;</seg>
  <seg  next="#s3b"  xml:id="s3a">with this key</seg>
</l>
<l>
  <seg  prev="#s3a"  xml:id="s3b">Shakespeare unlocked his heart;</seg>
  <seg  next="#s4b"  xml:id="s4a">the melody</seg>
</l>
<l>
  <seg  prev="#s4a"  xml:id="s4b">Of this small lute gave ease to Petrarch's
wound.</seg>
</l>
```

This method of virtually joining partial elements is sometimes called 'chaining'.

For fragments encoded using <ab>, <l>, <lg>, , or elements that belong to the `att.segLike` class, an even simpler mechanism for virtually joining fragments exists: the use of the *part* attribute with the value *I* (Initial), *M*

(Medial), or *F* (Final) as described in *17.3. Blocks, Segments, and Anchors.* Here is the above example recoded to reflect this method:

```
<l>
  <seg>Scorn not the sonnet;</seg>
  <seg  part="I">critic, you have frowned,</seg>
</l>
<l>
  <seg  part="F">Mindless of its just honours;</seg>
  <seg  part="I">with this key</seg>
</l>
<l>
  <seg  part="F">Shakespeare unlocked his heart;</seg>
  <seg  part="I">the melody</seg>
</l>
<l>
  <seg  part="F">Of this small lute gave ease to Petrarch's wound.</seg>
</l>
```

This method is TEI-conformant and simple to use. Its disadvantage is that it does not work well for cases of self-overlap, or if there are nested occurrences of the same element type, as it can become difficult to ascertain which initial, medial, or final partial element should be combined with which others or in which order. This problem becomes evident if we attempt to combine a detailed Grammatical view of the Pinsky example with its metrical encoding:

```
<lg>
  <l>
    <seg  part="I">Catholic woman of twenty-seven with five children</seg>
  </l>
  <l>
    <seg  part="M">And a first-rate body—pointed her finger</seg>
  </l>
  <l>
    <seg  part="M">at the back of one certain man and asked me,</seg>
  </l>
  <l>
    <seg  part="F">"<seg>Is that guy a psychiatrist?</seg>" and by god he was!</seg>
    <seg  part="I">"<seg  part="I">Yes,</seg>"</seg>
  </l>
  <l>
    <seg  part="F">She said, "<seg  part="F">He <emph>looks</emph> like a
psychiatrist.</seg>"</seg>
  </l>
  <l>
    <seg>Grown quiet, I looked at his pink back, and thought.</seg>
  </l>
</lg>
```

A third method for aggregating fragmented partial elements involves using markup that is not directly part of the encoding, e.g., the <join> element. In this method, a <join> element is used elsewhere in the document to indicate explicitly the members of the virtual element:

```
<l>
  <w  xml:id="w01">Scorn</w>
```

```
  <w  xml:id="w02">not</w>
  <w  xml:id="w03">the</w>
  <w  xml:id="w04">sonnet</w>; <w  xml:id="w05">critic</w>, <w  xml:id="w06">you</w>
  <w  xml:id="w07">have</w>
  <w  xml:id="w08">frowned</w>,
</l>
<l>
  <w  xml:id="w09">Mindless</w>
  <w  xml:id="w10">of</w>
  <w  xml:id="w11">its</w>
  <w  xml:id="w12">just</w>
  <w  xml:id="w13">honours</w>; <w  xml:id="w14">with</w>
  <w  xml:id="w15">this</w>
  <w  xml:id="w16">key</w>
</l>
<l>
  <w  xml:id="w17">Shakespeare</w>
  <w  xml:id="w18">unlocked</w>
  <w  xml:id="w19">his</w>
  <w  xml:id="w20">heart</w>; <w  xml:id="w21">the</w>
  <w  xml:id="w22">melody</w>
</l>
<l>
  <w  xml:id="w23">Of</w>
  <w  xml:id="w24">this</w>
  <w  xml:id="w25">small</w>
  <w  xml:id="w26">lute</w>
  <w  xml:id="w27">gave</w>
  <w  xml:id="w28">ease</w>
  <w  xml:id="w29">to</w>
  <w  xml:id="w30">Petrarch's</w>
  <w  xml:id="w31">wound</w>.
</l>
<!-- Elsewhere in the document -->
<p>
  <join  result="s"  scope="root"
    target="#w01 #w02 #w03 #w04"/>
  <join  result="s"  scope="root"
    target="#w05 #w06 #w07 #w08 #w09 #w10 #w11 #w12 #w13"/>
  <join  result="s"  scope="root"
    target="#w14 #w15 #w16 #w17 #w18 #w19 #w20"/>
  <join  result="s"  scope="root"
    target="#w21 #w22 #w23 #w24 #w25 #w26 #w27 #w28 #w29 #w30 #w31"/>
</p>
```

This use of <join> is TEI-conformant.

The major advantage of fragmentation and virtual joins is that it allows all the hierarchies in the text to be handled explicitly: both the privileged one directly represented and the alternate hierarchy that has been split up and rejoined. The major disadvantages are that (like most of the other methods described here) it privileges one hierarchy over the others, requires special processing to reconstitute the elements of the other hierarchies, and, except in the case of <join>, can be semantically misleading.

21.4 Stand-off Markup

Most markup is characterized by the embedding of elements in the text. An alternative approach separates the text and the elements used to describe it. This approach is known as stand-off markup (see section *17.9. Stand-off Markup*). It establishes a new hierarchy by building a new tree whose nodes are XML elements that do not contain

textual content, but rather links to another *layer*: *a node in another XML document or a span of text.* This approach can be subdivided according to different criteria. A first distinction concerns the link base, i.e. the content to which annotations are to be applied. Sometimes the link target contains markup that can be referred to explicitly, as in the following example where the offset markup uses the *xml:id* values on <w> to provide targets for `<xi:include>`[127]:

```
<l>
  <w  xml:id="w001">Scorn</w>
  <w  xml:id="w002">not</w>
  <w  xml:id="w003">the</w>
  <w  xml:id="w004">sonnet</w>; <w  xml:id="w005">critic</w>, <w  xml:id="w006">you</w>
  <w  xml:id="w007">have</w>
  <w  xml:id="w008">frowned</w>,
</l>
<l>
  <w  xml:id="w009">Mindless</w>
  <w  xml:id="w010">of</w>
  <w  xml:id="w011">its</w>
  <w  xml:id="w012">just</w>
  <w  xml:id="w013">honours</w>; <w  xml:id="w014">with</w>
  <w  xml:id="w015">this</w>
  <w  xml:id="w016">key</w>
</l>
<l>
  <w  xml:id="w017">Shakespeare</w>
  <w  xml:id="w018">unlocked</w>
  <w  xml:id="w019">his</w>
  <w  xml:id="w020">heart</w>; <w  xml:id="w021">the</w>
  <w  xml:id="w022">melody</w>
</l>
<l>
  <w  xml:id="w023">Of</w>
  <w  xml:id="w024">this</w>
  <w  xml:id="w025">small</w>
  <w  xml:id="w026">lute</w>
  <w  xml:id="w027">gave</w>
  <w  xml:id="w028">ease</w>
  <w  xml:id="w029">to</w>
  <w  xml:id="w030">Petrarch's</w>
  <w  xml:id="w031">wound</w>.
</l>
<!-- elsewhere in the current document -->

<p xmlns:xi="http://www.w3.org/2001/XInclude">
<seg>
<xi:include xpointer="range(element(w001),element(w004))"/>
</seg>
<seg>
<xi:include xpointer="range(element(w005),element(w013))"/>
</seg>
<seg>
<xi:include xpointer="range(element(w014),element(w020))"/>
</seg>
<seg>
<xi:include xpointer="range(element(w021),element(w031))"/>
```

[127] A fake namespace is given for XInclude here, to avoid the markup being interpreted literally during processing.

```
</seg>
</p>
```

Note that the layer that uses XInclude to build another hierarchy might well be in another document, in which case the value of *href* of `<xi:xinclude>` would need to be the URL of the document that contains the base layer, in this case the <w> elements.

This is very similar to the use of <join> discussed above. The main advantages of the stand-off method are that it is possible to specify attributes on the aggregate <seg> elements, and that there exists off-the-shelf software that will perform appropriate processing. Stand-off markup may be used even when the base text being annotated is plain text, i.e. does not have any XML encoding. In this case, the range of text to be marked up is indicated by character offsets (see *17.2.4. TEI XPointer Schemes*, in particular *17.2.4.7. string-range()*). Another distinction concerns the number of files which can serve as link targets. Often, one (dedicated) annotation is used as the link target of all the other annotations. It is also possible to freely interlink several layers.

It has been noted that stand-off markup has several advantages over embedded annotations. In particular, it is possible to produce annotations of a text even when the source document is read-only. Furthermore, annotation files can be distributed without distributing the source text. Further advantages mentioned in the literature are that discontinuous segments of text can be combined in a single annotation, that independent parallel coders can produce independent annotations, and that different annotation files can contain different layers of information. Lastly, it has also been noted that this approach is elegant.

But there are also several drawbacks. First, new stand-off annotated layers require a separate interpretation, and the layers—although separate—depend on each other. Moreover, although all of the information of the multiple hierarchies is included, the information may be difficult to access using generic methods.

Inasmuch as it uses elements not included in the TEI namespace, stand-off markup involves an extension of the TEI.

21.5 Non-XML-based Approaches

There exist many non-XML methods of encoding a text that either solve or do not suffer the problem of the inability to encode overlapping hierarchies. These include, but are not limited to, the following proposals.

- Applying the notion of concurrent markup to XML (**?**). This reintroduces the CONCUR feature of SGML, which was omitted from the XML specification.
- Designing a form of document representation in which several trees share all or part of the same frontier, and in which each individual view of the document has the form of a tree (see **?**).
- The 'colored XML' proposal (**?**), which stores a body of information as a set of intertwined XML trees. This approach eliminates unnecessary redundancy and makes the database readily updatable, while allowing the user to exploit different hierarchical access paths.
- The MultiX proposal (**?**) , which represents documents as directed graphs. Because XML is used to represent the graph, the document is, at least in principle, manipulable with standard XML tools.
- The Just-In-Time-Trees proposal (**?**), which stores documents using XML, but processes the XML representation in non-standard ways and allows it to be mapped onto data structures that are different from those known from XML.
- The Layered Markup and Annotation Language (LMNL) proposal. This offers alternatives to the basic XML linear form as well as its data and processing models. It uses an alternative notation to XML and a data structure based on Core Range Algebra (**?**).
- Markup Languages for Complex Documents (MLCD). This provides a notation (TexMECS) and a data structure (Goddag) as well as a draft constraint language for the representation of non-hierarchical structures; see **?**.

These approaches are based either on non-standard XML processing or data models, or not based on XML at all. Since TEI is currently based on XML they are not described any further in these Guidelines. Use of these methods with the TEI will certainly involve extensions; in most cases the documents will also be non-conformant.

22 Certainty, Precision, and Responsibility

Encoders of text often find it useful to indicate that some aspects of the encoded text are problematic or uncertain, and to indicate who is responsible for various aspects of the markup of the electronic text. These Guidelines provide several methods of recording uncertainty about the text or its markup:

- the <note> element defined in section *3.9. Notes, Annotation, and Indexing* may be used with a value of certainty for its *type* attribute.
- the <certainty> element defined in this chapter may be used to record the nature and degree of the uncertainty in a more structured way.
- the <precision> element defined in this chapter may be used to record the accuracy with which some numerical value (such as a date or quantity) is provided by some other element or attribute.
- the <alt> element defined in the module for linking and segmentation may be used to provide alternative encodings for parts of a text, as described in section *17.8. Alternation*.

There are three methods of indicating responsibility for different aspects of the electronic text:

- the TEI header records who is responsible for an electronic text by means of the <respStmt> element and other more specific elements (<author>, <sponsor>, <funder>, <principal>, etc.) used within the <titleStmt>, <editionStmt>, and <revisionDesc> elements.
- the <note> element may be used with a value of resp or responsibility in its *type* attribute.
- the <respons> element defined in this chapter may be used to record fine-grained structured information about responsibility for individual tags in the text.

No special steps are needed to use the <note> and <respStmt> elements, since they are defined in the core module and header respectively. The <alt> element is only available when the module for linking has been selected, as described in chapter *17. Linking, Segmentation, and Alignment.* To use the <certainty>, <precision> or <respons> elements, the module for certainty and responsibility should be selected.

These three elements are all members of an attribute class called `att.scoping` from which they inherit the following attributes:

`att.scoping` provides attributes for selecting particular elements within a document.

`@target` points at one or more sets of zero or more elements each.

`@match` supplies an XPath selection pattern using the syntax defined in **?** which identifies a set of nodes, selected within the context identified by the *target* attribute if this is supplied, or within the context of the parent element if it is not.

These attributes enable statements about certainty, precision, or responsibility to be made with respect to the whole of a document, or any part or parts of it which can be identified using standard XML location methods. Several examples are given in the discussion of the <certainty> element below; the same mechanisms are available for all three elements discussed in this chapter.

22.1 Levels of Certainty

Many types of uncertainty may be distinguished. The <certainty> element is designed to encode the following sorts:

- a given tag may or may not correctly apply (e.g. a given word may be a personal name, or perhaps not)
- the precise point at which an element begins or ends is uncertain
- the value given for an attribute is uncertain
- the content given for an element is unreliable for any reason.

The following types of uncertainty are *not* indicated with the <certainty> element:

- the numerical precision associated with a number or date (for this use the <precision> element discussed in *22.2. Indications of Precision*)
- the content of the document being transcribed is identifiable, but may be read or understood in different ways (for this use the transcriptional elements such as <unclear>, discussed in chapter *12. Representation of Primary Sources*)

- a transcriber, editor, or author wishes to indicate a level of confidence in a factual assertion made in the text (for this use the interpretative mechanisms discussed in *18. Simple Analytic Mechanisms* and *19. Feature Structures*)

22.1.1 Using Notes to Record Uncertainty

The simplest way of recording uncertainty about markup is to attach a note to the element or location about which one is unsure. In the following (invented) paragraph, for example, an encoder might be uncertain whether to mark 'Essex' as a place name or a personal name, since both might be plausible in the given context:

> Elizabeth went to Essex. She had always liked Essex.

Using <note>, the uncertainty here may be recorded quite simply:

```
<persName>Elizabeth</persName> went to <placeName>Essex</placeName>. She had always
liked <placeName>Essex</placeName>.
<note  type="certainty"  resp="#MSM">It is not
clear here whether <mentioned>Essex</mentioned>
refers to the place or to the nobleman. -MSM</note>
```

Using the normal mechanisms, the note may be associated unambiguously with specific elements of the text, thus:

```
<persName>Elizabeth</persName> went to <placeName  xml:id="CE-p1a">Essex</placeName>.
She had always liked <placeName  xml:id="CE-p1b">Essex</placeName>.
<note  type="certainty"  resp="#MSM"
  target="#CE-p1a #CE-p1b">It
is not clear here whether <mentioned>Essex</mentioned>
refers to the place or to the nobleman. If the latter,
it should be tagged as a personal name. -<name  xml:id="MSM">Michael</name>
</note>
```

The advantage of this technique is its relative simplicity. Its disadvantage is that the nature and degree of uncertainty are not conveyed in any systematic way and thus are not susceptible to any sort of automatic processing.

22.1.2 Structured Indications of Uncertainty

To record uncertainty in a more structured way, susceptible of at least simple automatic processing, the <certainty> element may be used:

`<certainty>` indicates the degree of certainty associated with some aspect of the text markup.

- `@locus` indicates more exactly the aspect concerning which certainty is being expressed: specifically, whether the markup is correctly located, whether the correct element or attribute name has been used, or whether the content of the element or attribute is correct, etc.
- `@degree` indicates the degree of confidence assigned to the aspect of the markup named by the *locus* attribute.

Returning to the example, the <certainty> element may be used to record doubts about the proper encoding of 'Essex' in several ways of varying precision. To record merely that we are not certain that 'Essex' is in fact a place name, as it is tagged, we use the *target* attribute to identify the element in question, and the *locus* attribute to indicate which aspect of the markup we are uncertain about (in this case, whether we have used the correct 'name' for the element used to mark it):

```
Elizabeth went to
<placeName  xml:id="CE-pl1">Essex</placeName>.

<!-- ... elsewhere in the document ... -->
<certainty  target="#CE-pl1"  locus="name">
  <desc>possibly not a placename</desc>
</certainty>
```

There are no particular constraints as to where the <certainty> element is placed in a document; it may be placed adjacent to the target element, or elsewhere in the same or another document. Its position is however significant when the *target* attribute is not specified as further discussed below.

We may wish to record the probability, assessed in some subjective way, that 'Essex' really is a place name here. The *degree* attribute is used to indicate the degree of confidence associated with the <certainty> element, expressed as a number between 0 and 1:

```
<!-- ... --><certainty  target="#CE-pl1"  locus="name"
  degree="0.6"/>
```

This expresses the point of view that there is a 60 percent chance of 'Essex' being a place name here, and hence a 40 percent chance of its being a personal name. We can use two <certainty> elements to indicate the two probabilities independently. Both elements indicate the same location in the text, but the second provides an alternative choice of name identifier (in this case <persName>), which is given as the value of the *assertedValue* attribute:

```
<!-- ... --><certainty  target="#CE-pl1"  locus="name"
  degree="0.6">
  <desc>probably a placename, but possibly not</desc>
</certainty>
<certainty  target="#CE-pl1"  locus="name"
  degree="0.4"  assertedValue="persName">
  <desc>may refer to the Earl of Essex</desc>
</certainty>
```

In the simplest case, it is also possible to place the <certainty> element within the element concerned:

```
Elizabeth went to
<placeName>Essex
<certainty  locus="name"  degree="0.6"/>
</placeName>.
```

When no *target* is specified, by default the proposed certainty applies to its parent element, in this case the <placeName> element. The *match* attribute discussed below may be used to further vary this behaviour.

22.1.2.1 Contingent Conditions

Finally, we may wish to make our probability estimates contingent on some condition. In the passage 'Elizabeth went to Essex; she had always liked Essex,' for example, we may feel there is a 60 percent chance that the county is meant, and a 40 percent chance that the earl is meant. But the two occurrences of the word are not independent: there is (we may feel) no chance at all that the first occurrence refers to the county and the second to the earl. We can express this by using the *given* attribute to list the identifiers of <certainty> elements.

```
Elizabeth went to <placeName  xml:id="CE-PL1">Essex</placeName>.
She had always liked <placeName  xml:id="CE-PL2">Essex</placeName>.

<!-- ... -->
<!-- 60% chance that P1 is a placename,
40% chance a personal name. -->
<certainty  xml:id="cert-1"  target="#CE-PL1"
  locus="name"  degree="0.6">
  <desc>probably a placename, but possibly not"</desc>
</certainty>
```

```
<certainty xml:id="cert-2" target="#CE-PL1"
  locus="name" assertedValue="persName" degree="0.4">
  <desc>may refer to the Earl of Essex"</desc>
</certainty>
<!-- 60% chance that P2 is a placename,
40% chance a personal name.
100% chance that it agrees with P1. -->
<certainty target="#CE-PL2" locus="name"
  given="#cert-1" degree="1.0">
  <desc>if CE-PL1 is a placename, CE-PL2 certainly is"</desc>
</certainty>
<certainty target="#CE-PL2" locus="name"
  assertedValue="persName" degree="1.0" given="#cert-2">
  <desc>if CE-PL1 is a personal name, then so is CE-PL2</desc>
</certainty>
```

When *given* conditions are listed, the <certainty> element is interpreted as claiming a given degree of confidence in a particular markup given the assertional content of the <certainty> elements indicated. That is, a conjectural assertion is being made solely on the assumption that the interpretation indicated by the element named by the *given* attribute is actually correct.

Conditional confidence may be less than 100 percent: given the sentence 'Ernest went to old Saybrook', we may interpret 'Saybrook' as a personal name or a place name, assigning a 60 percent probability to the former. If it is a place name, there may be a 50 percent chance that the place name actually in question is 'Old Saybrook' rather than 'Saybrook', while if it is correctly tagged as a personal name, it is much more likely (say, 90 percent certain) that the name is 'Saybrook'. Hence there is uncertainty about the correct location for the markup as well as about which markup to use. This state of affairs can be expressed using the <certainty> element thus:

```
Ernest went to <anchor xml:id="CE-a1"/> old <persName xml:id="CE-p2">Saybrook</persName>.

<certainty xml:id="cert1" target="#CE-p2"
  locus="name" degree="0.6"/>
<certainty target="#CE-p2" locus="start"
  given="#cert1" degree="0.9"/>
<certainty xml:id="cert2" target="#CE-p2"
  locus="name" assertedValue="placeName" degree="0.4"/>
<certainty target="#CE-p2" locus="start"
  given="#cert2" degree="0.5"/>
<certainty xml:id="cert3" target="#CE-p2"
  locus="start" assertedValue="#CE-a1" given="#cert1"
  degree="0.1"/>
<certainty xml:id="cert4" target="#CE-p2"
  locus="start" assertedValue="#CE-a1" given="#cert2"
  degree="0.5"/>
```

Note the use of the *assertedValue* on <certainty> elements cert3 and cert4 to reference the <anchor> element placed at the alternative starting point for the element.

Multiplying the numeric values out, this markup may be interpreted as assigning specific probabilities to three different ways of marking up the sentence:

```
Ernest went to old <persName>Saybrook</persName>. (0.6 * 0.9, or 0.54)
Ernest went to old <placeName>Saybrook</placeName>. (0.4 * 0.5, or 0.20)
Ernest went to <placeName>old Saybrook</placeName>. (0.4 * 0.5, or 0.20)
```

The probabilities do not add up to 1.00 because the markup indicates that if 'Saybrook' is (part of) a personal name, there is a 10 percent likelihood that the element should start somewhere other than the place indicated, without however giving an alternative location; there is thus a 6 percent chance (0.1 × 0.6) that none of the alternatives given is correct.

22.1.2.2 Pervasive Conditions

We may also wish to indicate confidence in some aspect of the tagging throughout a document, rather than (as discussed so far) in one particular instance. The *match* attribute may be used to supply a pattern identifying the portion of a document concerning which certainty is being expressed. The value of the *match* attribute is an XSLT selection pattern using the syntax defined in ?. In the following example, we wish to indicate a low degree of confidence that the <persName> elements used throughout the whole document have been correctly applied:

```
<certainty locus="name" degree="0.3"
  match="//persName"/>
```

No *target* has been supplied here, and so by default the <certainty> expressed would therefore apply to the parent element. However, in this case the XPath supplied as the value for *match* returns a set of all the <persName> elements in the document, independent of the current context. By contrast, in the following example

```
<div>
  <p>[...]</p>
</div>
<div>
  <certainty locus="name" degree="0.3"
    match=".//persName"/>
</div>
```

only the <persName> elements within the second element are in question. Similarly, we may indicate that we have more confidence in the <persName> tagging within those elements which have a *type* value of `checked`:

```
<certainty locus="name" degree="0.7"
  match="//div[@type='checked']//persName"/>
```

If an element in a document is matched by more than one match expression, then the most specific pattern applies. [128] As a simple case, if both the preceding <certainty> elements were present in the same document, a <persName> occurring within a element would potentially match both pattern expressions. However because the second pattern is more specific than the former, in fact this is the only one that would apply. If multiple patterns match and have the same priority, then the first one (in document order) is applied. Only those statements of certainty which have matched in this sense are available for conditional application using the *given* attribute mentioned above.

When the *match* attribute is processed, the namespace bindings in force are those in effect at that point in the document. For example,

```
<div>
<!-- ... -->
  <certainty match=".//my:*" locus="value"
    degree="0.9"/>
</div>
```

might be used to indicate a high degree of certainty about the content of any elements taken the namespace associated with the prefix `my`. This namespace prefix must be associated with an appropriate namespace definition, either on the <certainty> element itself, or on one of its ancestor elements.

[128] Specificity of pattern matching is defined further in the XSLT3 reference cited above (see `https://www.w3.org/TR/xslt-30/#default-priority`)

22.1.2.3 Content Uncertainty

Doubts about whether the content of an element is correct may also be expressed by assigning to *locus* the value *value*. For example, if the source is hard to read and so the transcription is uncertain:

```
I have a <emph  xml:id="CE-p3">bun</emph>.

<certainty  target="#CE-p3"  locus="value"
  degree="0.5"/>
```

Degrees of confidence in the proper expansion of abbreviations may also be expressed, as in the following example:

```
You will want to use
<choice>
  <expan  xml:id="CE-e1">Standard
     Generalized Markup Language</expan>
  <expan  xml:id="CE-e40">Some Grandiose Methodology for Losers</expan>
  <abbr>SGML</abbr>
</choice> ...

<!-- ... -->
<certainty  target="#CE-e1"  locus="value"
  degree="0.9"/>
<certainty  target="#CE-e40"  locus="value"
  degree="0.5"/>
```

The *assertedValue* attribute should be used to provide an alternative value for whatever aspect of the markup is in doubt: an alternative name, or the identifier of an alternative starting or ending point, as already shown, an alternative attribute value, or alternative element content, as in this example:

```
I have a <emph  xml:id="CE-P3">bun</emph>.

<certainty  target="#CE-P3"  locus="value"
  assertedValue="gun"  degree="0.8">
  <desc>a gun makes more sense in a holdup</desc>
</certainty>
```

Since attribute values have no internal substructure, the *assertedValue* attribute is not generally useful for specifying alternative transcriptions; it cannot for example be used if the alternative reading contains markup of any kind. More robust methods of handling uncertainties of transcription are the <unclear> element and the <app> and <rdg> elements described in chapter *13. Critical Apparatus*. The <certainty> element allows for indications of uncertainty to be structured with at least as much detail and clarity as appears to be currently required in most ongoing text projects.

22.1.2.4 Target or Match?

As noted in *17. Linking, Segmentation, and Alignment*, the *target* attribute may take any general teidata.pointer as values and may thus also contain an XPath expression of arbitrary complexity. Because full support for XPath is not provided by current processors, it is not generally recommended TEI practice. There are however some simple cases in which XPath syntax is to be preferred, notably those in which the *xml:id* attribute is used to identify a single element occurrence. The usage #A (to indicate the element whose *xml:id* attribute has the value A) is syntactically much simpler than the equivalent xpath2 expression //*[@xml:id='A'] and is hence preferred throughout these guidelines.

For similar reasons, the <certainty> element may specify both a *target* value (expressed as an URI) and a *match* value (expressed as an XPath). The former defines the context within which the latter is to be evaluated. As previously

noted, if no value is supplied for *target*, the context within which the value of *match* should be evaluated is the parent element of the <certainty> element itself.

A typical case where it may be convenient to specify both *target* and *match* is that where we wish to indicate that the value of an attribute on some specific element is uncertain. In this case, the *locus* attribute takes the value value. For example, supposing there is only a 50 percent chance that the question was spoken by participant A:

```
<u xml:id="CE-u1" who="#A">Have you heard the election results?</u>
<certainty target="#CE-u1" match="@who"
 locus="value" degree="0.5"/>
```

or, equivalently and without the need to define a target,

```
<u who="#A">Have you heard the election results?<certainty match="@who" locus="value"
   degree="0.5"/>
</u>
```

The *match* and *target* attributes together provide a powerful mechanism which can be used to indicate precision for a large number of assertions throughout an encoded document in an economical way. Some further examples follow:

```
<certainty match="//p" locus="location"
 degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the boundaries of all <p> elements in the document have been correctly identified.

```
<certainty target="#a101" match="p"
 locus="location" degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the boundaries of the <p> elements contained by the element with *xml:id* value a101 have been correctly identified.

```
<persName resp="#LB">Essex
<certainty match="@resp" locus="value"
   degree="0.2"/>
</persName>
```

This encoding indicates that there is only a 0.2 certainty that the value for the *resp* attribute on the given <persName> element is correct.

```
<certainty match="//*/@resp" locus="value"
 degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that any value for the *resp* attribute is correct, wherever it appears in the document.

```
<certainty target="#dd001" match="@resp"
 locus="value" degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the value for the *resp* attribute of the element indicated by the pointer #dd001 is correct

```
<certainty match="//*[@resp='#LB']"
  locus="value" degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the content of any element the *resp* attribute of which has the value #LB is correct, wherever it appears in the document.

The <certainty> element and the other TEI mechanisms for indicating uncertainty provide a range of methods of graduated complexity. Simple expressions of uncertainty may be made by using the <note> element. This is simple and convenient, and can accommodate either a discursive and unstructured indication of uncertainty, or a complex and structured but probably project-specific expression of uncertainty. In general, however, unless special steps are taken, the <note> element does not provide as much expressive power as the <certainty> element, and in cases where highly structured certainty information are needed, it is recommended that the <certainty> element be preferred.

22.2 Indications of Precision

As noted above, certainty about the accuracy of an encoding or its content is not the same thing as the *precision* with which a value is specified. In the case of a date or a quantity, for example, we might be certain that the value given is imprecise, or uncertain about whether or not the value given is correct. The latter possibility would be represented by the <certainty> element discussed in the previous section; the former by the <precision> element discussed in this section.

The elements concerning which statements of precision are to be made are identified using the same *target* and *match* attributes inherited from the `att.scoping` class discussed in the previous section and in the same way. Other aspects are provided by other attributes as further discussed below.

`<precision>` indicates the numerical accuracy or precision associated with some aspect of the text markup.

- `@precision` characterizes the precision of the element or attribute pointed to by the <precision> element.
- `@stdDeviation` supplies a standard deviation associated with the value in question.

In *3.6.3. Numbers and Measures* several ways of indicating ranges of values were introduced. For example, if we know that a date falls between 1930 and 1935, without being certain exactly where, this fact may be encoded using attributes *notBefore* and *notAfter*, as in the following example:

```
<date notBefore="1930" notAfter="1935">Early in the 1930s</date>...
```

Equally, if we know that every page of a manuscript has a width of at least 10 cm but no more than 30, we can use the attributes *atLeast* and *atMost*, as in the following examples:

```
<width atLeast="10" atMost="30" unit="cm"
  scope="all"/>
```

Suppose however that the precision with which the value of such an attribute can be specified is variable. For example, suppose an event is dated 'about fifty years after the death of Augustus'. In this case, the precision of one end of the range (the death of Augustus) is higher than the other, assuming we know when Augustus died. We can say that the latest possible date is probably 50 years after that, but with less confidence than we can attach to the earliest possible date.

The <precision> element allows us to indicate the two attributes concerned and attach different levels of precision to them, using a similar mechanism as that provided for the <certainty> element:

```
<date xml:id="d001" notBefore="0014"
 notAfter="0064">About 50
years after the death of Augustus</date>
<precision target="#d001" match="@notAfter"
 precision="low"/>
<precision target="#d001"
 match="@notBefore" precision="high"/>
```

In much the same way, we may wish to indicate different levels of precision about the dating of either end of a historical period. For example, the elements defined for encoding personal data all bear a similar set of attributes to indicate normalized values for earliest or latest dates, etc. (see section *14.1.2. Dating Attributes*); the precision of these attribute values may be indicated in exactly the same way. For example,

```
<residence from="1857-03-01"
 notAfter="1857-04-30">From the 1st of March to
some time in April of 1857.
<precision match="@notAfter"
   precision="medium"/>
</residence>
```

It may also be useful to indicate that the precisions given for minimum and maximum quanta differ. For example, to indicate that all pages measure at least 10 cm wide, and at most *about* 30:

```
<width xml:id="w00t" atLeast="10"
 atMost="30" unit="cm" scope="all"/>
<precision target="#w00t" match="@atMost"
 precision="low"/>
```

The *stdDeviation* attribute may be used to indicate the standard deviation for a range of values. The generic <dim> element introduced in *11.3.4. Dimensions* might be used to record the average number of characters per line in a typescript. If in addition we wish to record the standard deviation for the values summarized by that average, this would require an additional <precision> element, as in the following example:

```
<dim xml:id="dim1" type="avgLineLength"
 unit="chars" quantity="62.4"/>
<precision target="#dim1" stdDeviation="4"/>
```

22.3 Attribution of Responsibility

In general, attribution of responsibility for the transcription and markup of an electronic text is made by <respStmt> elements within the header: specifically, within the title statement, the edition statement(s), and the revision history.

In some cases, however, more detailed element-by-element information may be desired. For example, an encoder may wish to distinguish between the individuals responsible for transcribing the content and those responsible for determining that a given word or phrase constitutes a proper noun. Where such fine-grained attribution of responsibility is required, the <respons> element can be used.

`<respons>` (responsibility) identifies the individual(s) responsible for some aspect of the content or markup of particular element(s).

`@locus` indicates the specific aspect of the encoding (markup or content) for which responsibility is being assigned.

This element allows one or more aspects of the markup to be attributed to a given individual. This element inherits the *target* and *match* attributes from the `att.scoping` class, in the same way as the <certainty> and

<precision> elements. Its *locus* attribute functions in the same way as that on the <certainty> element (see *22.1. Levels of Certainty*). It inherits the *resp* and *cert* attributes from the `att.global.responsibility` class.

For example, the following encoding indicates that RC is responsible for transcribing an illegible word, and that PMWR is responsible for identifying that word as a proper noun, i.e. deciding to mark it with the <persName> element at the location indicated:

```
Ernest went to old
<persName xml:id="CE-p5" rend="it">Saybrook</persName>.

<!-- ... -->
<respons target="#CE-p5" locus="value"
  resp="#RC"/>
<respons target="#CE-p5"
  locus="name location" resp="#PMWR"/>
<list type="encoders">
  <item xml:id="PMWR"/>
  <item xml:id="RC"/>
</list>
```

Similarly, in the following example, we indicate that RC is responsible for proposing the value of the *rend* attribute:

```
<respons target="#CE-p5" match="@rend"
  locus="value" resp="#RC"/>
```

22.4 The Certainty Module

The module described in this chapter makes available the following additional elements:

Module certainty: Certainty, Precision, and Responsibility

- *Elements defined*: certainty precision respons

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

23 Documentation Elements

This chapter describes a module which may be used for the documentation of the XML elements and element classes which make up any markup scheme, in particular that described by the TEI Guidelines, and also for the automatic generation of schemas or DTDs conforming to that documentation. It should be used also by those wishing to customize or modify these Guidelines in a conformant manner, as further described in chapters *24.3. Customization* and *24.4. Conformance* and may also be useful in the documentation of any other comparable encoding scheme, even though it contains some aspects which are specific to the TEI and may not be generally applicable.

An overview of the kind of processing environment envisaged for the module described by this chapter may be helpful. In the remainder of this chapter we refer to software which provides such a processing environment as an *ODD processor*.[129] Like any other piece of XML software, an ODD processor may be instantiated in many ways: the current system uses a number of XSLT stylesheets which are freely available from the TEI, but this specification makes no particular assumptions about the tools which will be used to provide an ODD processing environment.

As the name suggests, an ODD processor uses a single XML document to generate multiple outputs. These outputs will include:

- formal reference documentation for elements, attributes, element classes, patterns, etc. such as those provided in *Appendix C Elements* below;
- detailed descriptive documentation, embedding some parts of the formal reference documentation, such as the tag description lists provided in this and other chapters of these Guidelines;
- declarative code for one or more XML schema languages, such as RELAX NG, W3C Schema, ISO Schematron, or DTD.

The input required to generate these outputs consists of running prose, and special purpose elements documenting the components (elements, classes, etc.) which are to be declared in the chosen schema language. All of this input is encoded in XML using elements defined in this chapter. In order to support more than one schema language, these elements constitute a comparatively high-level model which can then be mapped by an ODD processor to the specific constructs appropriate for the schema language in use. Although some modern schema languages such as RELAX NG or W3C Schema natively support self-documentary features of this kind, we have chosen to retain the ODD model, if only for reasons of compatibility with earlier versions of these Guidelines. For reasons of backwards compatibility, the ISO standard XML schema language RELAX NG (`http://www.relaxng.org`) may be used as a means of declaring content models and datatypes, but it is also possible to express content models using native TEI XML constructs. We also use the ISO Schematron language to define additional constraints beyond those expressed in the content model, as further discussed in *23.5.2. Additional Constraints* below.

In the TEI system, a *schema* is built by combining element and attribute declarations, more or less as required. Each element is documented by an appropriate *specification element* and has an identifier unique across the whole TEI scheme. For convenience, these specifications are grouped into a number of discrete *modules*, which can also be combined more or less as required. Each major chapter of these Guidelines defines a distinct module. Each module declares a number of *elements* specific to that module, and may also populate particular *classes*. All classes are available globally, irrespective of the module in which they are declared; particular modules extend the meaning of a class by adding elements or attributes to it. Wherever possible, element content models are defined in terms of classes rather than in terms of specific elements. Modules can also declare particular *patterns*, which act as short-cuts for commonly used content models or class references.

In the present chapter, we discuss the components needed to support this system. In addition, section *23.1. Phrase Level Documentary Elements* discusses some general purpose elements which may be useful in any kind of technical documentation, wherever there is need to talk about technical features of an XML encoding such as element names and attributes. Section *23.2. Modules and Schemas* discusses the elements which are used to document XML *modules* and their high-level components. Section *23.3. Specification Elements* discusses the elements which document XML elements and their attributes, element classes, and generic patterns or macros. Finally, section *23.9. Module for Documentation Elements* provides a summary overview of the elements provided by this module.

[129] ODD is short for 'One Document Does it all', and was the name invented by the original TEI Editors for the predecessor of the system currently used for this purpose. See further **?** and ?.

23.1 Phrase Level Documentary Elements

23.1.1 Phrase Level Terms

In any kind of technical documentation, the following phrase-level elements may be found useful for marking up strings of text which need to be distinguished from the running text because they come from some formal language:

`<code>` contains literal code from some formal language such as a programming language.

`@lang` (formal language) a name identifying the formal language in which the code is expressed.

`<ident>` (identifier) contains an identifier or name for an object of some kind in a formal language. <ident> is used for tokens such as variable names, class names, type names, function names etc. in formal programming languages.

Like other phrase-level elements used to indicate the semantics of a typographically distinct string, these are members of the `model.emphLike` class. They are available anywhere that running prose is permitted when the module defined by this chapter is included in a schema.

The <code> and <ident> elements are intended for use when citing brief passages in some formal language such as a programming language, as in the following example:

```
<p>If the variable <ident>z</ident> has a value of zero, a statement such as
<code>x=y/z</code> will
usually cause a fatal error.</p>
```

If the cited phrase is a mathematical or chemical formula, the more specific <formula> element defined by the `figures` module (*15.2. Formulæ and Mathematical Expressions*) may be more appropriate.

A further group of similar phrase-level elements is also defined for the special case of representing parts of an XML document:

`<att>` (attribute) contains the name of an attribute appearing within running text.

`<gi>` (element name) contains the name (generic identifier) of an element.

`<tag>` (tag) contains text of a complete start- or end-tag, possibly including attribute specifications, but excluding the opening and closing markup delimiter characters.

`<val>` (value) contains a single attribute value.

These elements constitute the `model.phrase.xml` class, which is also a subclass of `model.phrase`. They are also available anywhere that running prose is permitted when the module defined by this chapter is included in a schema.

As an example of the recommended use of these elements, we quote from an imaginary TEI working paper:

```
<p>The <gi>gi</gi> element is used to tag element
names when they appear in the text; the <gi>tag</gi> element however is used to show
how a tag as
such might appear. So one might talk of an occurrence of the <gi>blort</gi> element
which had been
tagged <tag>blort type='runcible'</tag>. The <att>type</att> attribute may take any
name token as
value; the default value is <val>spqr</val>, in memory of its creator.</p>
```

Within technical documentation, it is also often necessary to provide more extended examples of usage or to present passages of markup for discussion. The following special elements are provided for these purposes:

`<eg>` (example) contains any kind of illustrative example.

`<egXML>` (example of XML) a single XML fragment demonstrating the use of some XML, such as elements, attributes, or processing instructions, etc., in which the <egXML> element functions as the root element.

Like the <code> element, the <egXML> element is used to mark strings of formal code, or passages of XML markup. The <eg> element may be used to enclose any kind of example, which will typically be rendered as a distinct block, possibly using particular formatting conventions, when the document is processed. It is a specialized

form of the more general <q> element provided by the TEI core module. In documents containing examples of XML markup, the <egXML> element should be used for preference, as further discussed below in *23.4.2. Exemplification of Components*, since the content of this element can be checked for well-formedness.

These elements are added to the class `model.egLike` when this module is included in a schema. That class is a part of the general `model.inter` class, thus permitting <eg> or <egXML> elements to appear either within or between paragraph-like elements.

23.1.2 Element and Attribute Descriptions

Within the body of a document using this module, the following elements may be used to reference parts of the specification elements discussed in section *23.3. Specification Elements*, in particular the brief prose descriptions these provide for elements and attributes.

`<specList>` (specification list) marks where a list of descriptions is to be inserted into the prose documentation.

`<specDesc>` (specification description) indicates that a description of the specified element, class, or macro should be included at this point within a document.

`@atts` (attributes) supplies attribute names for which descriptions should additionally be obtained.

TEI practice recommends that a <specList> listing the elements under discussion introduce each subsection of a module's documentation. The source for the present section, for example, begins as follows:

```
<div>
  <head>Element and Attribute Descriptions</head>
  <p>Within the body of a document using this module, the following elements may be
used to reference parts of the specification elements
    discussed in section <ptr  target="#TDcrystals"/>, in particular the brief prose
descriptions these provide for elements and attributes.
  <specList>
     <specDesc  key="specList"/>
     <specDesc  key="specDesc"  atts="atts"/>
   </specList>
  </p>
  <p>TEI practice recommends that a <gi>specList</gi> listing the elements under … </p>
<!-- ... -->
</div>
```

When formatting the <ptr> element in this example, an ODD processor might simply generate the section number and title of the section referred to, perhaps additionally inserting a link to the section. In a similar way, when processing the <specDesc> elements, an ODD processor may recover relevant details of the elements being specified (<specList> and <specDesc> in this case) from their associated declaration elements: typically, the details recovered will include a brief description of the element and its attributes. These, and other data, will be stored in a specification element elsewhere within the current document, or they may be supplied by the ODD processor in some other way, for example from a database. For this reason, the link to the required specification element is always made using a TEI-defined key rather than an XML IDREF value. The ODD processor uses this key as a means of accessing the specification element required. There is no requirement that this be performed using the XML ID/IDREF mechanism, but there is an assumption that the identifier be unique.

A <specDesc> generates in the documentation the identifier, and also the contents of the <desc> child of whatever specification element is indicated by its *key* attribute, as in the example above. Documentation for any attributes specified by the *atts* attribute will also be generated as an associated attribute list.

23.2 Modules and Schemas

As mentioned above, the primary purpose of this module is to facilitate the documentation and creation of an XML schema derived from the TEI Guidelines. The following elements are provided for this purpose:

`<schemaSpec>` (schema specification) generates a TEI-conformant schema and documentation for it.

`<moduleSpec>` (module specification) documents the structure, content, and purpose of a single module, i.e. a named and externally visible group of declarations.

`<moduleRef>` (module reference) references a module which is to be incorporated into a schema.

`@include` supplies a list of the elements which are to be copied from the specified module into the schema being defined.

`@except` supplies a list of the elements which are not to be copied from the specified module into the schema being defined.

`<specGrp>` (specification group) contains any convenient grouping of specifications for use within the current module.

`<specGrpRef>` (reference to a specification group) indicates that the declarations contained by the <specGrp> referenced should be inserted at this point.

`<attRef>` (attribute pointer) points to the definition of an attribute or group of attributes.

`<elementRef>` points to the specification for some element which is to be included in a schema.

A *module* is a convenient way of grouping together element and other declarations, and of associating an externally-visible name with the resulting group. A *specification group* performs essentially the same function, but the resulting group is not accessible outside the scope of the ODD document in which it is defined, whereas a module can be accessed by name from any TEI schema specification. Elements, and their attributes, element classes, and patterns are all individually documented using further elements described in section *23.3. Specification Elements* below; part of that specification includes the name of the module to which the component belongs.

An ODD processor generating XML DTD or schema fragments from a document marked up according to the recommendations of this chapter will generate such fragments for each <moduleSpec> element found. For example, the chapter documenting the TEI module for names and dates contains a module specification like the following:

```
<moduleSpec  ident="namesdates">
  <idno  type="FPI">Names and Dates</idno>
  <desc>Additional elements for names and dates</desc>
</moduleSpec>
```

together with specifications for all the elements, classes, and patterns which make up that module, expressed using <elementSpec>, <classSpec>, or <macroSpec> elements as appropriate. (These elements are discussed in section *23.3. Specification Elements* below.) Each of those specifications carries a *module* attribute, the value of which is `namesdates`. An ODD processor encountering the <moduleSpec> element above can thus generate a schema fragment for the TEI `namesdates` module that includes declarations for all the elements (etc.) which reference it.

In most realistic applications, it will be desirable to combine more than one module together to form a complete *schema*. A schema consists of references to one or more modules or specification groups, and may also contain explicit declarations or redeclarations of elements (see further *23.8.1. TEI customizations*). Any combination of modules can be used to create a schema [130]

A schema can combine references to TEI modules with references to other (non-TEI) modules using different namespaces, for example to include mathematical markup expressed using MathML in a TEI document. By default, the effect of combining modules is to allow all of the components declared by the constituent modules to coexist (where this is syntactically possible: where it is not—for example, because of name clashes—a schema cannot be generated). It is also possible to over-ride declarations contained by a module, as further discussed in section *23.8.1. TEI customizations*

It is often convenient to describe and operate on sets of declarations smaller than the whole, and to document them in a specific order: such collections are called *specGrps* (specification groups). Individual <specGrp> elements are identified using the global *xml:id* attribute, and may then be referenced from any point in an ODD document using the <specGrpRef> element. This is useful if, for example, it is desired to describe particular groups of elements in a specific sequence. Note however that the order in which element declarations appear within the schema code generated from an ODD file element is not in general affected by the order of declarations within a <specGrp>.

An ODD processor will generate a piece of schema code corresponding with the declarations contained by a <specGrp> element in the documentation being output, and a cross-reference to such a piece of schema code when processing a <specGrpRef>. For example, if the input text reads

[130] The distinction between base and additional tagsets in earlier versions of the TEI scheme has not been carried forward into P5.

```
<p>This module contains three red elements: <specGrp  xml:id="RED">
   <elementSpec  ident="beetroot">
<!-- ... -->
   </elementSpec>
   <elementSpec  ident="east">
<!-- ... -->
   </elementSpec>
   <elementSpec  ident="rose">
<!-- ... -->
   </elementSpec>
  </specGrp> and two blue ones: <specGrp  xml:id="BLUE">
   <elementSpec  ident="sky">
<!-- ... -->
   </elementSpec>
   <elementSpec  ident="bayou">
<!-- ... -->
   </elementSpec>
  </specGrp>
</p>
```

then the output documentation will replace the two <specGrp> elements above with a representation of the schema code declaring the elements `<beetroot>`, `<east>`, and `<rose>` and that declaring the elements `<sky>` and `<bayou>` respectively. Similarly, if the input text contains elsewhere a passage such as

```
<div>
  <head>An overview of the imaginary module</head>
  <p>The imaginary module contains declarations for coloured things:
<specGrpRef  target="#RED"/>
   <specGrpRef  target="#BLUE"/>
  </p>
</div>
```

then the <specGrpRef> elements may be replaced by an appropriate piece of reference text such as 'The RED elements were declared in section 4.2 above', or even by a copy of the relevant declarations. As stated above, the order of declarations within the imaginary module described above will not be affected in any way. Indeed, it is possible that the imaginary module will contain declarations not present in any specification group, or that the specification groups will refer to elements that come from different modules. Specification groups are always local to the document in which they are defined, and cannot be referenced externally (unlike modules).

23.3 Specification Elements

The following elements are used to specify elements, classes, patterns, and datatypes:

`<elementSpec>` (element specification) documents the structure, content, and purpose of a single element type.

`<classSpec>` (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both.

- `@generate` indicates which alternation and sequence instantiations of a model class may be referenced. By default, all variations are permitted.

`<macroSpec>` (macro specification) documents the function and implementation of a pattern.

`<dataSpec>` (datatype specification) documents a datatype.

Unlike most elements in the TEI scheme, each of these 'specification elements' has a fairly rigid internal structure consisting of a large number of child elements which are always presented in the same order. Furthermore, since these elements all describe markup objects in broadly similar ways, they have several child elements in common. In

the remainder of this chapter, we discuss first the elements which are common to all the specification elements, and then those which are specific to a particular type.

Specification elements may appear at any point in an ODD document, both between and within paragraphs as well as inside a <specGrp> element, but the specification element for any particular component may only appear once (except in the case where a modification is being defined; see further *23.8.1. TEI customizations*). The order in which they appear will not affect the order in which they are presented within any schema module generated from the document. In documentation mode, however, an ODD processor will output the schema declarations corresponding with a specification element at the point in the text where they are encountered, provided that they are contained by a <specGrp> element, as discussed in the previous section. An ODD processor will also associate all declarations found with the nominated module, thus including them within the schema code generated for that module, and it will also generate a full reference description for the object concerned in a catalogue of markup objects. These latter two actions always occur irrespective of whether or not the declaration is included in a <specGrp>.

23.4 Common Elements

This section discusses the child elements common to all of the specification elements; some of these are defined in the core module (*3.4.1. Terms and Glosses*). These child elements are used to specify the naming, description, exemplification, and classification of the specification elements.

23.4.1 Description of Components

`<gloss>` (gloss) identifies a phrase or word used to provide a gloss or definition for some other word or phrase.

`<desc>` (description) contains a short description of the purpose, function, or use of its parent element, or when the parent is a documentation element, describes or defines the object being documented.

`<equiv>` (equivalent) specifies a component which is considered equivalent to the parent element, either by co-reference, or by external link.

- `@uri` (uniform resource identifier) references the underlying concept of which the parent is a representation by means of some external identifier.
- `@filter` references an external script which contains a method to transform instances of this element to canonical TEI.
- `@name` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), naming the underlying concept of which the parent is a representation.
- `@predicate [att.predicate]` the condition under which the element bearing this attribute applies, given as an XPath predicate expression.

`<altIdent>` (alternate identifier) supplies the recommended XML name for an element, class, attribute, etc. in some language.

`<listRef>` (list of references) supplies a list of significant references in the current document or elsewhere.

`<remarks>` (remarks) contains any commentary or discussion about the usage of an element, attribute, class, or entity not otherwise documented within the containing element.

The <gloss> element may be used to provide a brief explanation for the name of the object if this is not self-explanatory. For example, the specification for the element <ab> used to mark arbitrary blocks of text begins as follows:

```
<elementSpec module="linking" ident="ab">
  <gloss>anonymous block</gloss>
<!--... -->
</elementSpec>
```

A <gloss> may also be supplied for an attribute name or an attribute value in similar circumstances:

```
<valList type="open">
  <valItem ident="susp">
    <gloss>suspension</gloss>
    <desc>the abbreviation provides the first letter(s) of the word or phrase, omitting
the
        remainder.</desc>
  </valItem>
  <valItem ident="contr">
    <gloss>contraction</gloss>
    <desc>the abbreviation omits some letter(s) in the middle.</desc>
  </valItem>
<!--...-->
</valList>
```

Note that the <gloss> element is needed to explain the significance of the identifier for an item only when this is not apparent, for example because it is abbreviated, as in the above example. It should not be used to provide a full description of the intended meaning (this is the function of the <desc> element), nor to comment on equivalent values in other schemes (this is the purpose of the <equiv> element), nor to provide alternative versions of the *ident* attribute value in other languages (this is the purpose of the <altIdent> element).

The contents of the <desc> element provide a brief characterization of the intended function of the object being documented in a form that permits its quotation out of context, as in the following example:

```
<elementSpec module="core" ident="foreign">
<!--... -->
  <desc xml:lang="en"
    versionDate="2007-07-21">identifies a word or phrase as belonging to some
     language other than that of the surrounding text. </desc>
<!--... -->
</elementSpec>
```

By convention, a <desc> element begins with a verb such as *contains*, *indicates*, *specifies*, etc. and contains a single clause.

Both the <gloss> and <desc> elements (in addition to <exemplum>, <remarks>, and <valDesc>) are members of `att.translatable`, and thus carry the *versionDate* attributre. Where specifications are supplied in multiple languages, these elements may be repeated as often as needed. Each such element should carry both an *xml:lang* and a *versionDate* attribute to indicate the language used and the date on which the translated text was last checked against its source.

The <equiv> element is used to document equivalencies between the concept represented by this object and the same concept as described in other schemes or ontologies. The *uri* attribute is used to supply a pointer to some location where such external concepts are defined. For example, to indicate that the TEI <death> element corresponds to the concept defined by the CIDOC CRM category E69, the declaration for the former might begin as follows:

```
<elementSpec module="namesdates"
  ident="death">
  <equiv name="E69"
    uri="http://cidoc.ics.forth.gr/"/>
  <desc>
<!--... -->
  </desc>
</elementSpec>
```

The <equiv> element may also be used to map newly-defined elements onto existing constructs in the TEI, using the *filter* and *name* attributes to point to an implementation of the mapping. This is useful when a TEI customization

(see *24.3. Customization*) defines 'shortcuts' for convenience of data entry or markup readability. For example, suppose that in some TEI customization an element `<bo>` has been defined which is conceptually equivalent to the standard markup construct <hi rend='bold'>. The following declarations would additionally indicate that instances of the `<bo>` element can be converted to canonical TEI by obtaining a filter from the URI specified, and running the procedure with the name `bold`. The *mimeType* attribute specifies the language (in this case XSL) in which the filter is written:

```
<elementSpec ident="bo"
  ns="http://www.example.com/ns/nonTEI">
  <equiv filter="http://www.example.com/equiv-filter.xsl"
    mimeType="text/xsl" name="bold"/>
  <gloss>bold</gloss>
  <desc>contains a sequence of characters rendered in a bold face.</desc>
<!-- ... -->
</elementSpec>
```

The <altIdent> element is used to provide an alternative name for an object, for example using a different natural language. Thus, the following might be used to indicate that the <abbr> element should be identified using the German word *Abkürzung*:

```
<elementSpec ident="abbr" mode="change">
  <altIdent xml:lang="de">Abkürzung</altIdent>
<!--...-->
</elementSpec>
```

In the same way, the following specification for the <graphic> element indicates that the attribute *url* may also be referred to using the alternate identifier `href`:

```
<elementSpec ident="graphic" mode="change">
  <attList>
    <attDef mode="change" ident="url">
      <altIdent>href</altIdent>
    </attDef>
<!-- ... -->
  </attList>
</elementSpec>
```

By default, the <altIdent> of a component is identical to the value of its *ident* attribute.

The <remarks> element contains any additional commentary about how the item concerned may be used, details of implementation-related issues, suggestions for other ways of treating related information etc., as in the following example:

```
<elementSpec module="core" ident="foreign">
<!--... -->
  <remarks>
    <p>This element is intended for use only where no other element is available to
mark the phrase
        or words concerned. The global <att>xml:lang</att> attribute should be used in
preference to
        this element where it is intended to mark the language of the whole of some
text element.</p>
    <p>The <gi>distinct</gi> element may be used to identify phrases belonging to
```

```
sublanguages or
        registers not generally regarded as true languages.</p>
  </remarks>
<!--... -->
</elementSpec>
```

A specification element will usually conclude with a list of references, each tagged using the standard <ptr> element, and grouped together into a <listRef> element: in the case of the <foreign> element discussed above, the list is as follows:

```
<listRef>
  <ptr  target="#COHQHF"/>
</listRef>
```

where the value COHQF is the identifier of the section in these Guidelines where this element is fully documented.

23.4.2 Exemplification of Components

<exemplum> (exemplum) groups an example demonstrating the use of an element along with optional paragraphs of commentary.

<eg> (example) contains any kind of illustrative example.

<egXML> (example of XML) a single XML fragment demonstrating the use of some XML, such as elements, attributes, or processing instructions, etc., in which the <egXML> element functions as the root element.

- *@valid* indicates the intended validity of the example with respect to a schema.
- *@source [att.global.source]* specifies the source from which some aspect of this element is drawn.

The <exemplum> element is used to combine a single illustrative example with an optional paragraph of commentary following or preceding it. The illustrative example itself may be marked up using either the <eg> or the <egXML> element.

The *source* attribute may be used on either element to indicate the source from which an example is taken, typically by means of a pointer to an entry in an associated bibliography, as in the following example:

```
  <exemplum versionDate="2008-04-06" xml:lang="fr">
  <p>L'element <gi>foreign</gi> s'applique également aux termes considerés étrangers.</p>
    <egXML xmlns="http://www.tei-c.org/ns/Examples" source="#fr-ex-Queneau_Journ">
      <p>Pendant ce temps-là, dans le bureau du rez- de-chaussée, les secrétaires faisaient du
        <foreign xml:lang="en">hulla-hoop</foreign>.</p>
    </egXML>
  </exemplum>
```

When, as here, an example contains valid XML markup, the <egXML> element should be used. In such a case, it will clearly be necessary to distinguish the markup within the example from the markup of the document itself. In an XML environment, this is easily done by using a different name space for the content of the <egXML> element. For example:

```
  <p>The <gi>term</gi> element may be used
to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples">
This <term>recursion</term> is
giving me a headache.</egXML></p>
```

Alternatively, the XML tagging within an example may be 'escaped', either by using entity references to represent the opening angle bracket, or by wrapping the whole example in a CDATA marked section:

```
  <p>The <gi>term</gi> element may be used
to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples">
This &lt;term&gt;recursion&lt;/term&gt; is
giving me a headache.</egXML></p>
```

or, equivalently:

```
  <p>The <gi>term</gi> element may be used
to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples"><![CDATA[
This <term>recursion</term> is
giving me a headache.]]></egXML></p>
```

However, escaping the markup in this way will make it impossible to validate, and should therefore generally be avoided.

If the XML contained in an example is not well-formed then it must either be enclosed in a CDATA marked section, or 'escaped' as above: this applies whether the <eg> or <egXML> is used. The *valid* attribute on <egXML> may be used to indicate the XML validity of the example with respect to some schema, as being valid, invalid, or feasibly valid.

The <egXML> element should not be used to tag non-XML examples: the general purpose <eg> or <q> elements should be used for such purposes.

23.4.3 Classification of Components

In the TEI scheme elements are assigned to one or more *classes*, which may themselves have subclasses. The following elements are used to indicate class membership:

`<classes>` (classes) specifies all the classes of which the documented element or class is a member or subclass.

`<memberOf>` specifies class membership of the documented element or class.

`@key` specifies the identifier for a class of which the documented element or class is a member or subclass.

The <classes> element appears within either the <elementSpec> or <classSpec> element. It specifies the classes of which the element or class concerned is a member by means of one or more <memberOf> child elements. Each such element references a class by means of its *key* attribute. Classes themselves are defined by the <classSpec> element described in section *23.6. Class Specifications* below.

For example, to show that the element <gi> is a member of the class `model.phrase.xml`, the <elementSpec> which documents this element contains the following <classes> element:

```
<classes>
  <memberOf  key="model.phrase.xml"/>
</classes>
```

23.5 Element Specifications

The <elementSpec> element is used to document an element type, together with its associated attributes. In addition to the elements listed above, it may contain the following subcomponents:

`<content>` (content model) contains a declaration of the intended content model for the element (or other construct) being specified.

`@autoPrefix` controls whether or not pattern names generated in the corresponding RELAX NG schema source are automatically prefixed to avoid potential nameclashes.

`<constraintSpec>` (constraint on schema) contains a formal constraint, typically expressed in a rule-based schema language, to which a construct must conform in order to be considered valid

`@scheme` supplies the name of the language in which the constraints are defined

`<attList>` (attribute list) contains documentation for all the attributes associated with this element, as a series of <attDef> elements.

`@org` (organization) specifies whether only one (choice) or all (group) of the attributes in the list are available.

`<model>` describes the processing intended for a specified element.

`@behaviour` names the process or function which this processing model uses in order to produce output.

These subcomponents are discussed in the following sections.

23.5.1 Defining Content Models

As described in *v.3.2 Content Models: an Example* and *Content Model*, the *content* of the element being defined — that is, what elements are allowed inside it, and in what order they are permitted — is described by its *content model*. The content model is defined by the <content> child of <elementSpec>. There are three distinctly different ways of specifying a content model:

- The content model can be described using TEI elements defined by this chapter, as discussed in *23.5.1.1. Defining Content Models: TEI* immediately below. Two such TEI elements that may be used to define a content model are <dataRef> and <valList>. But because these are most often used to define attribute values, they are discussed separately near the beginning and towards the end of *23.5.3.2. Value Specification*, respectively.
- Alternatively, and primarily for backwards compatibility, the content model may be expressed using a RELAX NG pattern. This is discussed in *23.5.1.2. Defining Content Models: RELAX NG*, below.
- Lastly, content models may be expressed using a schema language other than TEI or RELAX NG, but no further recommendations on doing so are provided by these Guidelines.

23.5.1.1 Defining Content Models: TEI

In the simplest case, the content model of an element may be expressed using a single <empty> element as the only child of <content>. This describes the element being defined as *empty*, meaning a valid instance of said element can not have any content.[131]

`<empty>` indicates the presence of an empty node within a content model.

More commonly, one or more of the following elements are used to define a content model:

`<elementRef>` points to the specification for some element which is to be included in a schema.

`<anyElement>` indicates the presence of any elements in a content model.

`<classRef>` points to the specification for an attribute or model class which is to be included in a schema.

`<macroRef>` points to the specification for some pattern which is to be included in a schema.

An <elementRef> provides the name of an element which may appear at a certain point in a content model. An <anyElement> also asserts that an element may appear at a certain point in a content model, but rather than providing the name of a particular element type that may appear, any element regardless of its name may appear (and may have any attributes). A <classRef> provides the name of a model class, members of which may appear at a certain point in content model.[132] A <macroRef> provides the name of a predefined macro, the expansion of which is to be inserted at a certain point in a content model.

These three elements are all members of an attribute class which provides attributes that further modify their significance as follows:

`att.repeatable` provides attributes for the elements which define component parts of a content model.

[131] It would still be allowed to contain comments or processing instructions, as these are not considered part of the content model.

[132] The <classRef> element may be used to refer to attribute classes, but this should not be done within a <content>.

@*minOccurs* (minimum number of occurrences) indicates the smallest number of times this component may occur.

@*maxOccurs* (maximum number of occurrences) indicates the largest number of times this component may occur.

Additionally, three wrapper elements are provided to indicate whether the components listed as their children form a sequence, an alternation, or are interleaved:

`<sequence>` indicates that the constructs referenced by its children form a sequence.

`<alternate>` indicates that the constructs referenced by its children form an alternation.

`<interleave>` indicates that the constructs referenced by its children occur in any order (i.e. are interleaved)

Note, however, that current ODD processing software will not be able to convert a content model that uses <interleave> to a DTD. These *Guidelines* recommend against using <interleave> when generating XSD schemas, as not all cases of interleave can be expressed in XSD (especially those that are likely to be the most useful).

These three wrapper elements are also members of `att.repeatable`. References listed as children of <sequence> must appear in the order and cardinality specified whereas references listed as children of <interleave> may appear in any order. Only one of the references listed as children of <alternate> may appear, although the cardinality of the <alternate> itself applies. Thus the following fanciful content model permits either any number of <ptr> elements (except zero) or any number of <ref> elements (except zero); at least one element must be present, but having both a <ptr> and a <ref> would be invalid.

```
<content>
  <alternate>
    <elementRef key="ptr" minOccurs="1"
      maxOccurs="unbounded"/>
    <elementRef key="ref" minOccurs="1"
      maxOccurs="unbounded"/>
  </alternate>
</content>
```

However, the following content model permits any number of either <ptr> or <ref> elements (except zero); one element must be present, and having both <ptr> elements and <ref> elements (even intermixed) would be valid.

```
<content>
  <alternate minOccurs="1"
    maxOccurs="unbounded">
    <elementRef key="ptr"/>
    <elementRef key="ref"/>
  </alternate>
</content>
```

The <sequence>, <alternate>, and <interleave> elements may be used in combination with great expressive power. For example, in the following example, which might be imagined as a clean replacement for the content of the <choice> element, one and only one of the element pairs <sic> and <corr>, <orig> and <reg>, or <abbr> and <expan> is allowed, in each case only in the order specified.

```
<content>
  <alternate>
    <sequence>
      <elementRef key="sic"/>
      <elementRef key="corr"/>
    </sequence>
    <sequence>
```

```
      <elementRef  key="orig"/>
      <elementRef  key="reg"/>
    </sequence>
    <sequence>
      <elementRef  key="abbr"/>
      <elementRef  key="expan"/>
    </sequence>
  </alternate>
</content>
```

In the above example, the alternation of element pairs must be encoded in the order specified (for example, <sic> and then <corr>). In the next example, which also might be imagined as a clean replacement for the content of the <choice> element, this restriction is removed. That is, one and only one of the element pairs <sic> and <corr>, <orig> and <reg>, or <abbr> and <expan> is allowed, but in each case the members of the pair may occur in either order.

```
<content>
  <alternate>
    <interleave>
      <elementRef  key="sic"/>
      <elementRef  key="corr"/>
    </interleave>
    <interleave>
      <elementRef  key="orig"/>
      <elementRef  key="reg"/>
    </interleave>
    <interleave>
      <elementRef  key="abbr"/>
      <elementRef  key="expan"/>
    </interleave>
  </alternate>
</content>
```

This next example, which might be imagined as a clean replacement for the content of the <person> element, declares that the element must contain one <persName> element, either both <birth> and <death> elements (in that order) or a single <floruit> element, and one <note> element in any order:

```
<content>
  <interleave>
    <elementRef  key="persName"/>
    <alternate  minOccurs="0"  maxOccurs="1">
      <sequence>
        <elementRef  key="birth"/>
        <elementRef  key="death"/>
      </sequence>
      <elementRef  key="floruit"/>
    </alternate>
    <elementRef  key="note"/>
  </interleave>
</content>
```

In the following example, which might be imagined as a clean replacement for the content of the <address> element, the encoder is given a choice of either:

- a single <street> followed by a single <placeName> followed by a single <postCode> followed by an optional <country>, or
- 2, 3, or 4 <addrLine> elements.

```
<content>
  <alternate>
    <sequence>
      <elementRef  key="street"/>
      <elementRef  key="placeName"/>
      <elementRef  key="postCode"/>
      <elementRef  key="country"  minOccurs="0"
        maxOccurs="1"/>
    </sequence>
    <elementRef  key="addrLine"  minOccurs="2"
      maxOccurs="4"/>
  </alternate>
</content>
```

In addition to expressing where certain elements, members of a class of elements, or constructs matching a predefined macro may occur inside an element, a content model may permit a string of zero or more Unicode characters to occur at a certain point in the content model. This is indicated by supplying the element <textNode> within the <content> element.

`<textNode>` indicates the presence of a text node in a content model.

If nothing but a <textNode> element is present inside a <content> element, valid instances of the element being defined may contain a sequence of zero or more Unicode characters, but may not contain any elements.[133]

23.5.1.2 Defining Content Models: RELAX NG

Element content models may also be defined using RELAX NG patterns. Here is a very simple example

```
<content>
  <rng:text/>
</content>
```

The element within whose specification element this <content> element appears will have a content model which is expressed in RELAX NG as `text`, using the RELAX NG namespace. This model will be copied unchanged to the output when RELAX NG schemas are being generated. When an XML DTD is being generated, an equivalent declaration (in this case `(#PCDATA)`) will be output.

Here is a more complex example:

```
<content>
  <rng:group>
    <rng:ref  name="fileDesc"/>
    <rng:zeroOrMore>
      <rng:ref  name="model.teiHeaderPart"/>
    </rng:zeroOrMore>
    <rng:optional>
      <rng:ref  name="revisionDesc"/>
    </rng:optional>
  </rng:group>
</content>
```

[133] This content model is not used very often in the TEI scheme. Because only Unicode characters are permitted, there is no way to record characters that are not (yet) represented in Unicode. Thus in TEI instead of <textNode> we often use a reference to `macro.xtext` which permits both Unicode characters and the <g> element.

This is the content model for the <teiHeader> element, expressed in the RELAX NG syntax, which again is copied unchanged to the output during schema generation. The equivalent DTD notation generated from this is `(fileDesc, (%model.teiHeaderPart;)*, revisionDesc?)`.

The RELAX NG language does not formally distinguish element names, attribute names, class names, or macro names: all names are patterns which are handled in the same way, as the above example shows. Within the TEI scheme, however, different naming conventions are used to distinguish amongst the objects being named. Unqualified names (`fileDesc`, `revisionDesc`) are always element names. Names prefixed with `model.` or `att.` (e.g. `model.teiHeaderPart` and `att.typed`) are always class names. In DTD language, classes are represented by parameter entities (`%model.teiHeaderPart;` in the above example); see further *1. The TEI Infrastructure*.

The RELAX NG pattern names generated by an ODD processor by default include a special prefix, the default value for which is set using the *prefix* attribute on <schemaSpec>. The purpose of this is to ensure that the pattern name generated is uniquely identified as belonging to a particular schema, and thus avoid name clashes. For example, in a RELAX NG schema combining the TEI element <ident> with another element called <ident> from some other vocabulary, the former will be defined by a pattern called `TEI_ident` rather than simply `ident`. Most of the time, this behaviour is entirely transparent to the user; the one occasion when it is not will be where a content model (expressed using RELAX NG syntax) needs explicitly to reference either the TEI <ident> or the other one. In such a situation, the *autoPrefix* attribute on <content> may be used. For example, suppose that we wish to define a content model for <term> which permits either a TEI <ident> or the <ident> defined by some other vocabulary. A suitable content model would be generated from the following <content> element:

```
<content autoPrefix="false">
  <rng:choice>
    <rng:ref name="TEI_ident"/>
    <rng:ref name="ident"/>
  </rng:choice>
</content>
```

23.5.2 Additional Constraints

In addition to the <content> element, a set of general <constraintSpec> elements can be used to express rules about the validity of an element. Like some other specification elements, they are identifiable (using the *ident* attribute) in order that a TEI customization may override, delete, or change them individually. Each <constraintSpec> can be expressed in any notation which is found useful; the notation used must be recorded using the *scheme* attribute.

Schematron is an ISO standard (ISO/IEC 19757-3:2006) that defines a simple XML vocabulary for an 'assertion language' which provides a powerful way of expressing constraints on the content of any XML document in addition to those provided by other schema languages. Such constraints can be embedded within a TEI schema specification — including a TEI customization specification — using the methods exemplified in this chapter.[134] An ODD processor will typically process any <constraintSpec> elements in a TEI specification whose *scheme* attribute indicates that they are expressed in Schematron to create an ISO Schematron schema which may be used to validate document instances. The ISO Schematron schema may be a free-standing document, or may be embedded in the RELAX NG schema output of the ODD processor.

Constraints are generally used to model local rules which may be outside the scope of the target schema language. For example, in earlier versions of these Guidelines several constraints on the usage of the attributes of the TEI element <relation> were expressed informally as follows: 'only one of the attributes *active* and *mutual* may be supplied; the attribute *passive* may be supplied only if the attribute *active* is supplied.'. In the current version of the Guidelines, constraint specifications expressed as Schematron rules have been added, as follows:

```
<constraintSpec ident="ref-or-key-or-name"
  scheme="schematron"
```

[134] Indeed, these *Guidelines* themselves include many additional constraints which are expressed in the ISO Schematron language using this mechanism. A conformant TEI document should respect these constraints, although automatic validation of them may not be possible for all processors.

```
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <sch:rule  context="tei:relation">
      <sch:assert  test="@ref or @key or @name">One of the attributes @name, @ref, or
@key must be supplied.</sch:assert>
    </sch:rule>
  </constraint>
</constraintSpec>
<constraintSpec  ident="active-mutual"
  scheme="schematron">
  <constraint>
    <sch:rule  context="tei:relation">
      <sch:report  test="@active and @mutual">Only one of the attributes @active and
@mutual may be supplied.</sch:report>
    </sch:rule>
  </constraint>
</constraintSpec>
<constraintSpec  ident="active-passive"
  scheme="schematron">
  <constraint>
    <sch:rule  context="tei:relation">
      <sch:report  test="@passive and not(@active)">the attribute @passive may be
supplied only if the attribute @active is supplied.</sch:report>
    </sch:rule>
  </constraint>
</constraintSpec>
```

Note that the 'tei:' prefix needs to be bound to the TEI namespace using the Schematron language `<ns>` element. This can be done using the <constraintDecl> element, which may appear in either the <encodingDesc> or <schemaSpec> element. A <constraintDecl> contains declarations specific to all the <constraintSpec> elements in the current TEI document whose *scheme* matches that of the <constraintDecl>.

```
<constraintDecl  scheme="schematron"
  queryBinding="xslt3"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <sch:ns  prefix="tei"
    uri="http://www.tei-c.org/ns/1.0"/>
  <sch:ns  prefix="xi"
    uri="http://www.w3.org/2001/XInclude"/>
  <sch:let  name="edition"
    value="substring-before( /*/tei:teiHeader//tei:editionStmt/tei:edition/@n, '.')"/>
  <sch:let  name="uses_old_encoding"
    value="$edition cast as xs:integer lt 3"/>
</constraintDecl>
```

In this example the Schematron query language binding is set (to xslt3) for use by a Schematron processor, two namespace prefixes are bound to namespace URIs for later use within <constraint> elements, and the `$uses_old_encoding` variable is set (to either `true()` or `false()`) so that Schematron assertions elsewhere in the TEI document can easily test whether the edition number of the document being checked is 3 or more. (Presumably in this project there are minor encoding differences between the older and newer editions which do not merit an entirely different schema, but do merit the occasional different constraint.)

The following two examples are written presuming that the <constraintDecl> above is in force, that is that the Schematron processor will use an xslt3 binding, that 'tei:' is bound to the TEI namespace, that 'xi:' is bound to the XInclude namespace, and that the variable `$uses_old_encoding` is defined as a boolean. The first example

models the constraint that a TEI must contain either no subdivisions or at least two of them, with the added complication that larger subdivisions are provided as separate sect*NN*.xml files read in using XInclude:

```
<constraintSpec ident="subclauses"
  scheme="schematron"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <sch:rule context="tei:div">
      <sch:report test="count( tei:div | xi:include[ contains( @href, 'sect') ] ) eq
1">If it contains any
           subdivisions, a division must contain at least two of them.</sch:report>
    </sch:rule>
  </constraint>
</constraintSpec>
```

The second example demonstrates that Schematron rules are also useful where an application needs to enforce rules on attribute values, in this case checking that various types of <title> are provided in the TEI header:

```
<constraintSpec ident="introtitle"
  scheme="schematron"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <sch:rule context="tei:teiHeader">
      <sch:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type='introductory']"> An
introductory component of the title is expected.
     </sch:assert>
    </sch:rule>
  </constraint>
</constraintSpec>
<constraintSpec ident="maintitle"
  scheme="schematron">
  <constraint>
    <sch:rule context="tei:teiHeader[ $uses_old_encoding ]">
      <sch:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type eq 'main']"> A main
title must be supplied.
     </sch:assert>
    </sch:rule>
    <sch:rule context="tei:teiHeader[ not( $uses_old_encoding ) ]">
      <sch:assert test="tei:fileDesc/tei:titleStmt/tei:title[ not( @type eq 'sub' ) ]">
A main title must be supplied.
     </sch:assert>
    </sch:rule>
  </constraint>
</constraintSpec>
```

As a further example, Schematron may be used to enforce rules applicable to a TEI document which is going to be rendered into accessible HTML, for example to check that some sort of content is available from which the *alt* attribute of an HTML `<img>` can be created:

```
<constraintSpec ident="alt"
  scheme="schematron"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <sch:pattern id="altTags">
```

```
     <sch:rule  context="tei:figure">
       <sch:assert  test="tei:figDesc or tei:head"> You should provide information in a
<figure> from
              which we can construct an @alt attribute in HTML.
       </sch:assert>
     </sch:rule>
   </sch:pattern>
  </constraint>
</constraintSpec>
```

Schematron rules can also be used to enforce other HTML accessibility rules about tables; note here the use of a report and an assertion within one pattern:

```
<constraintSpec  ident="tables"
  scheme="schematron"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <sch:pattern  id="Tables">
      <sch:rule  context="tei:table">
        <sch:assert  test="tei:head">A <table> should have a caption, using a <head>
element.</sch:assert>
       <sch:report  test="parent::tei:body">Do not use tables to lay out the document
body.</sch:report>
      </sch:rule>
    </sch:pattern>
  </constraint>
</constraintSpec>
```

Constraints can be expressed using any convenient language. The following example uses a pattern matching language called SPITBOL to express the requirement that title and author should be different.

```
<constraintSpec  ident="title_ne_author"
  scheme="SPITBOL">
  <constraint> (output = leq(title,author) "title and author cannot be the same")
</constraint>
</constraintSpec>
```

Note that the value of *scheme* is SPITBOL. In order to properly constrain and document the values of *scheme* used in their customization file, a project may wish to create a customization that (among other things) adds and explains this value for use in validating their customization file. Thus using schemes other than those provided for by the TEI (currently only schematron) may require somewhat more effort when creating a customization file. Such private schemes will generally be even more problematic on implementation of the constraints themselves, as it may require significant programming work. The TEI only provides this capability for the suggested value (schematron).

23.5.3 Attribute List Specification

The <attList> element is used to document information about a collection of attributes, either within an <elementSpec>, or within a <classSpec>. An attribute list can be organized either as a group of attribute definitions, all of which are understood to be available, or as a choice of attribute definitions, of which only one is understood to be available. An attribute list may thus contain nested attribute lists.

The attribute *org* is used to indicate whether its child <attDef> elements are all to be made available, or whether only one of them may be used. For example, the attribute list for the element <moduleRef> contains a nested attribute list to indicate that either the *include* or the *except* attribute may be supplied, but not both:

```
<attList>
<!-- other attribute definitions here -->
  <attList org="choice">
    <attDef ident="include">
<!-- definition for the include attribute -->
    </attDef>
    <attDef ident="except">
<!-- definition for the except attribute -->
    </attDef>
  </attList>
</attList>
```

The <attDef> element is used to document a single attribute, using an appropriate selection from the common elements already mentioned and the following :

`<attDef>` (attribute definition) contains the definition of a single attribute.

`@usage` specifies the optionality of the attribute.

`<datatype>` (datatype) specifies the declared value for an attribute, by referring to any datatype defined by the chosen schema language.

`@minOccurs` (minimum number of occurrences) indicates the minimum number of times this datatype may occur in an instance of the attribute being defined.

`@maxOccurs` (maximum number of occurrences) indicates the maximum number of times this datatype may occur in an instance of the attribute being defined.

`<dataRef>` identifies the datatype of an attribute value, either by referencing an item in an externally defined datatype library, or by pointing to a TEI-defined data specification

`<defaultVal>` (default value) specifies the default declared value for an attribute.

`<valDesc>` (value description) specifies any semantic or syntactic constraint on the value that an attribute may take, additional to the information carried by the <datatype> element.

`<valList>` (value list) contains one or more <valItem> elements defining possible values.

`<valItem>` documents a single value in a predefined list of values.

The <attList> within an <elementSpec> is used to specify only the attributes which are specific to that particular element. Instances of the element may carry other attributes which are declared by the classes of which the element is a member. These extra attributes, which are shared by other elements, or by all elements, are specified by an <attList> contained within a <classSpec> element, as described in section *23.6. Class Specifications* below.

23.5.3.1 Datatypes

The 'datatype' (i.e. the kind of value) for an attribute may be specified using the elements <datatype> and <dataRef>. A datatype may be defined in any of the following three ways:

- by reference to an existing TEI datatype definition, itself defined by a <dataSpec>;
- by use of its name in XML Schema Part 2: Datatypes Second Edition, the widely used datatype library maintained by the W3C as part of the definition of its schema language;
- by referencing its URI within some other datatype library.

The TEI defines a number of datatypes, each with an identifier beginning `teidata.`, which are used in preference to the datatypes available natively from a target schema such as RELAX NG or W3C Schema since the facilities provided by different schema languages vary so widely. The TEI datatypes available are described in section *1.4.2. Datatype Specifications* above. Note that each is, of necessity, mapped eventually to an externally defined datatype such as W3C Schema's `text` or `name`, possibly combined to give more expressivity, or constrained to a particular defined usage.

It is possible to reference a W3C schema datatype directly using *name*. In this case, the child <dataFacet> can be used instead of *restriction* to set W3C schema compliant restrictions on the datatype. A <dataFacet> is particularly useful for restrictions that can be difficult to impose and to read as a regular expression pattern.

```
<dataRef  name="decimal">
  <dataFacet  name="maxInclusive"
    value="360.0"/>
  <dataFacet  name="minInclusive"
    value="-360.0"/>
</dataRef>
```

Note that restrictions are either expressed with *restriction* or <dataFacet>, never both.

A datatype may be used to constrain the textual content of an element, rather than the value of an attribute. But because they are intended for use in defining ranges of attribute values, datatypes may not contain elements or attributes.

The attributes *minOccurs* and *maxOccurs* are available for the case where an attribute may take more than one value of the type specified. For example, the *columns* attribute of the <layout> element can have one or two non-negative integers as its value:

```
<attDef  ident="columns">
  <gloss  xml:lang="en"
    versionDate="2007-06-12">columns</gloss>
  <desc  versionDate="2005-01-14"
    xml:lang="en">specifies the number of columns per page</desc>
  <datatype  minOccurs="1"  maxOccurs="2">
    <dataRef  key="teidata.count"/>
  </datatype>
  <remarks  xml:lang="en"
    versionDate="2017-07-09">
    <p>If a single number is given, all pages referenced
        have this number of columns. If two numbers are given,
        the number of columns per page varies between the
        values supplied. Where <att>columns</att> is omitted
        the number is assumed to be <val>1</val>.</p>
  </remarks>
</attDef>
```

indicating that the *target* attribute may take any number of values, each being of the same datatype, namely the TEI data specification `teidata.pointer`. As is usual in XML, multiple values for a single attribute are separated by one or more white space characters. Hence, values such as `#a #b #c` or `http://example.org http://www.tei-c.org/index.xml` may be supplied.

23.5.3.2 Value Specification

The <valDesc> element may be used to describe constraints on data content in an informal way: for example

```
<valDesc>must point to another <gi>align</gi>
element logically preceding this one.</valDesc>
```

```
<valDesc>Values should be Library of Congress
subject headings.</valDesc>
```

```
<valDesc>A bookseller's surname, taken from the list
in <title>Pollard and Redgrave</title>
</valDesc>
```

Constraints expressed in this way are purely documentary; to enforce them, the <constraintSpec> element described in section *23.5.2. Additional Constraints* must be used. For example, to specify that an imaginary attribute *ageAtDeath* must take positive integer values less than 150, the datatype `teidata.numeric` might be used in combination with a <constraintSpec> such as the following:

```
<attDef ident="ageAtDeath"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>age in years at death</desc>
  <datatype>
    <dataRef key="teidata.count"/>
  </datatype>
  <constraintSpec ident="lessThan150"
    scheme="schematron">
    <constraint>
      <sch:rule context="@ageAtDeath">
        <sch:assert test=". le 150">Age at death must be an integer less than
150.</sch:assert>
      </sch:rule>
    </constraint>
  </constraintSpec>
</attDef>
```

The elements <altIdent>, <equiv>, <gloss> and <desc> may all be used in the same way as they are elsewhere to describe fully the meaning of a coded value, as in the following example:

```
<valItem ident="dub">
  <altIdent xml:lang="fr">dou</altIdent>
  <equiv name="unknown"/>
  <gloss>dubious</gloss>
  <desc>used when the application of this element is doubtful or uncertain</desc>
</valItem>
```

Where all the possible values for an attribute can be enumerated, the datatype `teidata.enumerated` should be used, together with a <valList> element specifying the values and their significance, as in the following example:

```
<valList type="closed">
  <valItem ident="req">
    <gloss>required</gloss>
  </valItem>
  <valItem ident="rec">
    <gloss>recommended</gloss>
  </valItem>
  <valItem ident="opt">
    <gloss>optional</gloss>
  </valItem>
</valList>
```

Note the use of the <gloss> element here to explain the otherwise less than obvious meaning of the codes used for these values. Since this value list specifies that it is of type closed, only the values enumerated are legal, and an ODD processor will typically enforce these constraints in the schema fragment generated.

The <valList> element can also be used to provide illustrative examples of the kinds of values expected without listing all of them. In such cases the *type* attribute will have the value open, as in the following example:

```
<attDef ident="type" usage="opt">
  <desc versionDate="2005-01-14"
    xml:lang="en">characterizes the movement, for example as an
     entrance or exit.</desc>
  <desc versionDate="2007-12-20"
    xml:lang="ko">예를 들어 입장 또는 퇴장과 같은, 이동의 특성을 기술한다.</desc>
  <datatype>
    <dataRef key="teidata.enumerated"/>
  </datatype>
  <valList type="open">
    <valItem ident="entrance">
      <desc versionDate="2007-06-27"
        xml:lang="en">character is entering the stage.</desc>
      <desc versionDate="2007-12-20"
        xml:lang="ko">등장인물이 무대에 등장하고 있다.</desc>
    </valItem>
    <valItem ident="exit">
      <desc versionDate="2007-06-27"
        xml:lang="en">character is exiting the stage.</desc>
      <desc versionDate="2007-12-20"
        xml:lang="ko">등장인물이 무대에서 퇴장하고 있다.</desc>
    </valItem>
    <valItem ident="onStage">
      <desc versionDate="2007-07-04"
        xml:lang="en">character moves on stage</desc>
      <desc versionDate="2007-12-20"
        xml:lang="ko">등장인물이 무대에서 이동한다.</desc>
    </valItem>
  </valList>
</attDef>
```

The datatype will be `teidata.enumerated` in either case.

The <valList> or <dataRef> elements may also be used (as a child of the <content> element) to put constraints on the permitted content of an element, as noted at *23.5.1.2. Defining Content Models: RELAX NG*. This use is not however supported by all schema languages, and is therefore not recommended if support for non-RELAX NG systems is a consideration.

23.5.4 Processing Models

As far as possible, the TEI defines elements and their attributes in a way which is entirely independent of their subsequent processing, since its intention is to maximize the reusability of encoded documents and their use in multiple contexts. Nevertheless, it can be very useful to specify one or more possible models for such processing, both to clarify the intentions of the encoder, and to provide default behaviours for a software engineer to implement when documents conforming to a particular TEI customization are processed. To that end, the following elements may be used to document one or more *processing models* for a given element.

`<model>` describes the processing intended for a specified element.

`<modelGrp>` (model group) any grouping of <model> or <modelSequence> elements with a common output method.

`<modelSequence>` any sequence of model or <modelSequence> elements which is to be processed as a single set of actions.

One or more of these elements may appear directly within an element specification to define the processing anticipated for that element, more specifically how it should be processed to produce the kind of output indicated by the *output* attribute. Where multiple such elements appear directly within an <elementSpec>, they are understood to document mutually exclusive processing models, possibly for different outputs or applicable in different contexts. Alternatively, the <modelGrp> element may be used to group alternative <model> elements intended for a single

kind of output. The <modelSequence> element is provided for the case where a sequence of models is to be processed, functioning as a single unit.

A processing model suggests how a given element may be transformed to produce one or more outputs. The model is expressed in terms of *behaviours* and *parameters*, using high-level formatting concepts familiar to software engineers and web designers, such as 'block' or 'inline'. As such, it has a different purpose from existing TEI mechanisms for documenting the appearance of source materials, such as the global attributes *rend*, *rendition* and *style*, described in sections *2.3.4.1. Rendition* and *3.3.1. What Is Highlighting?*. It does not necessarily describe anything present in the original source, nor does it necessarily represent its original structure or semantics. A processing model is a template description, which may be used to simplify the task of producing or customizing the stylesheets needed by a formatting engine or any other form of processor.

23.5.4.1 The TEI processing model

The <model> element is used to document the processing model intended for a particular element in an abstract manner, independently of its implementation in whatever processing language is chosen. This is achieved by means of the following attributes and elements:

`<model>` describes the processing intended for a specified element.

- `@predicate [att.predicate]` the condition under which the element bearing this attribute applies, given as an XPath predicate expression.
- `@behaviour` names the process or function which this processing model uses in order to produce output.
- `@output` the intended output.
- `@useSourceRendition` whether to obey any rendition attribute that is present.
- `@cssClass` the name of a CSS class which should be associated with this element

`<outputRendition>` describes the rendering or appearance intended for all occurrences of an element in a specified context for a specified type of output.

- `@scope` provides a way of defining 'pseudo-elements', that is, styling rules applicable to specific sub-portions of an element.

The mandatory *behaviour* attribute defines in broad terms how an element should be processed, for example as a block or as an inline element. The optional *predicate* attribute may be used to specify a subset of contexts in which this model should be applicable: for example, an element might be treated as a block element in some contexts, but not in others. The *output* attribute supplies a name for the output for which this model is intended, for example for screen display, for a printed reading copy, for a scholarly publication, etc. The way in which an element should be rendered is declared independently of its behaviour, using either the attribute *useSourceRendition* or the element <outputRendition>. These Guidelines recommend that <outputRendition> be expressed using the W3C Cascading Stylesheet Language (CSS), but other possibilities are not excluded. The particular language used may be documented by means of the <styleDefDecl> element described in *2.3.5. The Default Style Definition Language Declaration*.

23.5.4.2 Output Rendition

Here is a simple example of a processing model which might be included in the specification for an element such as <hi> or <foreign>. The intent is that these elements should be presented inline using an italic font.

```
<model behaviour="inline">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

If the <rendition> element, or the attributes *style*, *rend*, or *rendition* have already been used in the source document to indicate elements that were originally rendered in italic, and we wish simply to follow this in our processing, then there is no need to include an <outputRendition> element, and the attribute *useSourceRendition* could be used as follows:

```
<model behaviour="inline"
  useSourceRendition="true"/>
```

Any rendition information present in the source document will be ignored unless the *useSourceRendition* attribute has the value true. If that is the case, then such information will be combined with any rendition information supplied by the <outputRendition> element. For example, using CSS, an element which appears in the source as follows

```
<hi  style="font-weight:bold;">this is in bold</hi>
```

would appear in bold and italic if processed by the following model

```
<model  behaviour="inline"
  useSourceRendition="true">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

23.5.4.3 CSS Class

In a typical workflow processing TEI documents for display on the web, a system designer will often wish to use an externally defined CSS stylesheet. The *cssClass* attribute simplifies the task of maintaining compatibility amongst the possibly many applications using such a stylesheet and also enables a TEI application to specify the names of classes to be used for particular processing models. For example, supposing that the associated CSS stylesheet includes a CSS class called `labeled-list`, the following processing model might be used to request it be used for <list> elements containing a child <label> element:

```
<elementSpec  ident="list"  mode="change">
  <model  predicate="label"  behaviour="list"
    cssClass="labeled-list">
<!-- ... -->
  </model>
</elementSpec>
```

In the following example, a table will be formatted using renditional information provided in the source if that is available, or by an external stylesheet, using one of the CSS classes specified, if it is not:

```
<elementSpec  mode="change"  ident="table">
<!-- Preserve original rendition for tables which contain @rendition hints -->
  <model  predicate=".//row/@rendition or .//cell/@rendition"
    behaviour="table"  useSourceRendition="true"/>
<!-- Use bootstrap for default table styling -->
  <model  behaviour="table"
    useSourceRendition="true"
    cssClass="table table-hover table-bordered"/>
</elementSpec>
```

As discussed further below, the input data available to a processing model is by default the content of the element being processed, together with its child nodes.

23.5.4.4 Model Contexts and Outputs

Sometimes different processing models are required for the same element in different contexts. For example, we may wish to process the <quote> element as an inline italic element when it appears inside a <p> element, but as an indented block when it appears elsewhere. To achieve this, we need to change the specification for the <quote> element to include two <model> elements as follows:

```
<elementSpec ident="quote" mode="change">
  <model predicate="ancestor::p"
    behaviour="inline">
    <outputRendition>font-style: italic;</outputRendition>
  </model>
  <model behaviour="block">
    <outputRendition>left-margin: 2em;</outputRendition>
  </model>
</elementSpec>
```

As noted above, these two models are mutually exclusive. The first processing model will be used only for <quote> elements which match the XPath expression given as value for the *predicate* attribute. All other element occurrences will use the second processing model.

When, as here, multiple behaviours are required for the same element, it will often be the case that the appropriate processing will depend on the context. It may however be the case that the choice of an appropriate model will be made on the basis of the intended output. For example, we might wish to define quite different behaviours when a document is to be displayed on a mobile device and when it is to be displayed on a desktop screen. Different behaviours again might be specified for a print version intended for the general reader, and for a print version aimed at the technical specialist.

The <modelGrp> element can be used to group together all the processing models which have in common a particular intended output, as in the following example:

```
<modelGrp output="mobile">
  <model behaviour="inline"
    predicate="@rend='inline'">
    <outputRendition>font-size: 7pt;</outputRendition>
  </model>
  <model behaviour="block"
    predicate="@rend='block'">
    <outputRendition>text-color: red;</outputRendition>
  </model>
</modelGrp>
<modelGrp output="print">
  <model behaviour="inline"
    predicate="@rend='inline'">
    <outputRendition>font-size: 12pt;</outputRendition>
  </model>
  <model behaviour="block"
    useSourceRendition="true" predicate="@rend='block'">
    <outputRendition>text-align: center;</outputRendition>
  </model>
</modelGrp>
```

23.5.4.5 Behaviours and their parameters

In the examples above we have used without explanation or definition two simple *behaviours*: `inline` and `block`, but many other behaviours are possible. A list of recommended behaviour names forms part of the specification for the element <model>. A processing model can specify any named behaviour, some of which have additional *parameters*. The `parameters` of a `behaviour` resemble the arguments of a function in many programming languages: they provide names which can be used to distinguish particular parts of the input data available to the process used to implement the behaviour in question.

The following elements are used to represent and to define parameters:

`<param>` provides a parameter for a model behaviour by supplying its name and an XPath expression identifying the location of its content.

`@name` a name for the parameter being supplied.

`<paramList>` list of parameter specifications.

`<paramSpec>` supplies specification for one parameter of a model behaviour.

By default, a processor implementing the TEI processing model for a particular element has available to it as input data the content of the element itself, and all of its children. One or more <param> elements may be supplied within a <model> element to specify *parameters* which modify this, either by selecting particular parts of the default input data, or by selecting data which would not otherwise be available. In either case, the value supplied for the parameter is given as an XPath expression, evaluated with respect to the element node being processed. An arbitrary name (defined in the corresponding <paramSpec>) is also supplied to a processor to identify each parameter.

For example, an element such as the TEI <ref> element will probably be associated with a processing model which treats it as a hyperlink. But a hyperlink (in most implementations) often has two associated pieces of information: the address indicated, and some textual content serving to label the link . In HTML, the former is provided as value of the *href* element, and the latter by the content of an `<a>` element. In the following processing model we define a behaviour called `link`, which will use whatever is indicated by the parameter called `uri` to provide the former, while the latter is provided by the content of the <ref> element itself:

```
<elementSpec ident="ref" mode="add">
  <model behaviour="link">
    <param name="uri" value="@target"/>
    <param name="content" value="."/>
  </model>
</elementSpec>
```

The *value* attribute of a <param> element supplies an XPath expression that indicates where the required value may be found. The context for this XPath is the element which is being processed; hence in this example, the `uri` parameter takes the value of the *target* attribute on the <ref> element being processed. The `content` parameter indicates that the content of that <ref> element should be provided as its value. (This parameter is not strictly necessary, since by default the whole content of the element being processed is always available to a processor, but supplying it in this way makes the procedure more explicit).

All the parameters available for a given behaviour are defined as a part of the definition of the behaviour itself, as further discussed in section *23.5.4.8. Defining a processing model* below.

As a further example, the TEI <choice> element requires a different behaviour for which the name `alternate` is proposed as in the following example:

```
<elementSpec ident="choice" mode="change">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
</elementSpec>
```

The processing model shown here will be selected for processing a <choice> element which has both <sic> and <corr> child elements. The names `default` and `alternate` here are provided for convenience. The `default` parameter provides the value of the child <corr> element, and the `alternate` parameter will provide that of the child <sic> elements. If neither <param> element was supplied, both elements would still be available to an application, but the application would need to distinguish them for itself.

A <choice> element might contain multiple corrections, each with differing values for their *cert* attribute. In the following processing model, we will accept as value of the `default` attribute only those child <corr> elements which have a value high for that attribute:

```
<elementSpec ident="choice" mode="change">
  <model predicate="sic and corr"
```

```
    behaviour="alternate">
    <param  name="default"
      value="corr[@cert='high']"/>
    <param  name="alternate"  value="sic"/>
  </model>
</elementSpec>
```

A <choice> element might contain several different pairs of alternate elements (<abbr> and <expan>, <orig> and <reg>, etc.) We might wish to group together a set of processing models for these, for example to determine which of the possible alternatives is displayed by default whenever a <choice> element is processed for output to the web:

```
<elementSpec  ident="choice"  mode="change">
  <modelGrp  output="web">
    <model  predicate="sic and corr"
      behaviour="alternate">
      <param  name="default"
        value="corr[@cert='high']"/>
      <param  name="alternate"  value="sic"/>
    </model>
    <model  predicate="abbr and expan"
      behaviour="alternate">
      <param  name="default"  value="expan[1]"/>
      <param  name="alternate"  value="abbr"/>
    </model>
    <model  predicate="orig and reg"
      behaviour="alternate">
      <param  name="default"  value="reg"/>
      <param  name="alternate"  value="orig"/>
    </model>
  </modelGrp>
</elementSpec>
```

If nothing matches the XPath defining the value of a particular parameter (e.g. if in the above example there is no correction with *cert*=high) then the `default` parameter has no value. It is left to implementors to determine how null-valued parameters should be processed.

23.5.4.6 Outputs

As noted above, the *output* attribute is used to associate particular processing models with a specific type of output. The following example documents a range of processing intentions for the <date> element, intended to cope with at least the following three situations:

1. there is text inside the element, and the output is print;
2. there is no text inside the element but there is a *when* attribute, and the output is print;
3. there is a *when* attribute, there is text inside the element, and the output is web

```
<elementSpec  ident="date"  mode="change">
  <modelGrp  output="print">
    <model  predicate="text()"
      behaviour="inline"/>
    <model  predicate="@when and not(text())"
      behaviour="inline">
      <param  name="content"  value="@when"/>
    </model>
```

```
  </modelGrp>
  <model output="web" predicate="@when"
    behaviour="alternate">
    <param name="default" value="."/>
    <param name="alternate" value="@when"/>
  </model>
</elementSpec>
```

For output to print we supply two processing models, one for the simplest case where the content of the <date> is to be treated as an inline element, and the other for the case where there is no content and the value of the *when* attribute is to be used in its place. This is specified by a parameter, called `content` in this example. For output to web, we use the `alternate` behaviour discussed in the previous section to indicate that by default the content of the element will be used, while retaining access to the value of the *when* attribute, this time via a parameter called `alternate`.

23.5.4.7 Model sequence

As well as being combined to form model groups, several models may be combined to form a *model sequence*. All of the individual components of a model sequence are understood to be applied, rather than considered to be mutually exclusive alternatives. For example, we might wish to define two different behaviours for a <note> element: the inline behaviour should be used to display the value of the note number (given by its *n* attribute), while a different behaviour (here called `footnote`) should be used to display the content of the element at a specified place, given by the parameter `place`. Because both of these actions are required, the two models are grouped by a <modelSequence> element:

```
<elementSpec ident="note" mode="change">
  <modelSequence output="print">
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
    <model behaviour="footnote">
      <param name="place" value="'foot'"/>
    </model>
  </modelSequence>
</elementSpec>
```

The value of the parameter called `place` above is an XPath expression supplying an arbitrary string ('foot'), which is therefore quoted. It is left to implementors to validate or constrain the possible values for such expressions.

23.5.4.8 Defining a processing model

The processing model for an element is defined using some combination of <model>, <modelSequence>, or <modelGrp> elements within the <elementSpec> element containing its specification. The processing to be carried out is defined by means of the behaviour specified for each <model> element, possibly supplying specified values for a number of named parameters. The parameters available for a given behaviour are specified using a number of <param> elements grouped together in a <paramList> element. This <paramList> is supplied within the <valItem> used to document and name the behaviour. Here for example is the <valItem> which defines the `link` behaviour presented above:

```
<valItem ident="link">
  <desc>create a hyperlink</desc>
  <paramList>
    <paramSpec ident="content">
      <desc>supplies the location of some content describing the link</desc>
    </paramSpec>
```

```
    <paramSpec ident="uri">
      <desc>supplies the location of the intended hyperlink</desc>
    </paramSpec>
  </paramList>
</valItem>
```

Similarly the <valItem> which defines the behaviour named `alternate` includes specifications for two parameters: one also called `alternate` and the other called `default`

```
<valItem ident="alternate">
  <desc versionDate="2015-08-21"
    xml:lang="en">support display of alternative visualisations, for
     example by displaying the preferred content, by displaying both in parallel, or by
toggling
     between the two.</desc>
  <paramList>
    <paramSpec ident="default">
      <desc versionDate="2015-08-21"
        xml:lang="en">supplies the location of the preferred
            content</desc>
    </paramSpec>
    <paramSpec ident="alternate">
      <desc versionDate="2015-08-21"
        xml:lang="en">supplies the location of the alternative
            content</desc>
    </paramSpec>
  </paramList>
</valItem>
```

The suggested behaviours provided by the <model> element are informally defined using commonly understood terminology, but specific details of how they should be implemented are left to the implementor. Such decisions may vary greatly depending on the kind of processing environment, the kind of output envisaged, etc. The intention is to reduce as far as possible any requirement for the implementor to be aware of TEI-specific rules, and to maximize the ability of the ODD to express processing intentions without fully specifying an implementation.

23.5.4.9 Implementation of Processing Models

As elsewhere in these Guidelines, the recommendations of this section are intended to be implementation-agnostic, not favouring any particular implementation method or technology. An implementor may choose, for example, whether to pre-process processing model specifications into a free standing 'pipeline', or to extract and process them dynamically during document processing. However, although implementors are generally free to interpret the processing model documentation according to their own requirements, some general assumptions underlie the recommendations made here:

- If a <model> element has no child <param> elements, the action specified by its behaviour should be applied to the whole element node concerned, including its child nodes of whatever type. If that behaviour requires distinguishing particular parts of the input, an implementation may choose either to make those distinctions itself, or to raise an error.
- If a <model> element has no *predicate* or *output* attribute then it is assumed to apply to all instances of the element defined in its parent <elementSpec> for all outputs. Otherwise its applicability depends on these attributes.
- Only one of the <model>s is to be applied for a particular instance of the element, except when they appear within a <modelSequence>
- A 'matching' model is one where the element to be processed satisfies the XPath in the *predicate* attribute of the <model> or <modelSequence> and the current output method matches the method specified in the *output* attribute of the <model>, <modelSequence>, or a containing <modelGrp>. A <model> or <modelSequence> without a

predicate always matches the element to be processed. A <model>, <modelGrp>, or <modelSequence> without an *output* attribute matches any output method.

- Processing Model implementations must execute only the first matching <model> or <modelSequence> in document order.
- If there are two or more <model> elements provided for an <elementSpec> but they have different *output* attributes then the implementation should choose the <model> appropriate to the desired output.
- If there are two or more <model> elements provided for an <elementSpec> but they have different *predicate* attributes then the implementation should choose the <model> whose *predicate* provides the most specific context (where *specific* is understood in the same way as in XSLT)

In the following example, which shows part of the element specification for the <head> element, there are two <model> elements, one with and one without a *predicate* attribute:

```
<model behaviour="inline"
  predicate="parent::list">
  <desc versionDate="2015-03-02"
    xml:lang="en">Model for list headings</desc>
<!-- ... -->
</model>
<model behaviour="heading">
  <desc versionDate="2016-03-02"
    xml:lang="en">Default model for all headings.</desc>
<!-- ... -->
</model>
```

In this example, an implementation should use the first processing model only for <head> elements with a <list> element as parent; for all other <head> elements, the second processing model should be used.

23.6 Class Specifications

The element <classSpec> is used to document either an *attribute class* or a 'model class', as defined in section *1.3. The TEI Class System*. A corresponding <classRef> element may be used to select a specific named class from those available.

`<classSpec>` (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both.
`@type` indicates whether this is a model class or an attribute class

`<classRef>` points to the specification for an attribute or model class which is to be included in a schema.
`@expand` indicates how references to this class within a content model should be interpreted.

`<attList>` (attribute list) contains documentation for all the attributes associated with this element, as a series of <attDef> elements.
`@org` (organization) specifies whether only one (choice) or all (group) of the attributes in the list are available.

A model class specification does not list all of its members. Instead, its members declare that they belong to it by means of a <classes> element contained within the relevant <elementSpec>. This will contain a <memberOf> element for each class of which the relevant element is a member, supplying the name of the relevant class. For example, the <elementSpec> for the element <hi> contains the following:

```
<classes>
  <memberOf key="model.hiLike"/>
</classes>
```

This indicates that the <hi> element is a member of the class with identifier `model.hiLike`. The <classSpec> element that documents this class contains the following declarations:

```
<classSpec  type="model"
  ident="model.hiLike">
  <desc>groups phrase-level elements related to highlighting that have no specific
semantics </desc>
  <classes>
    <memberOf  key="model.highlighted"/>
  </classes>
</classSpec>
```

which indicate that the class `model.hiLike` is actually a member (or subclass) of the class `model.highlighted`.

The function of a model class declaration is to provide another way of referring to a group of elements. It does not confer any other properties on the elements which constitute its membership.

The attribute *type* is used to distinguish between 'model' and 'attribute' classes. In the case of attribute classes, the attributes provided by membership in the class are documented by an <attList> element contained within the <classSpec>. In the case of model classes, no further information is needed to define the class beyond its description, its identifier, and optionally any classes of which it is a member.

When a model class is referenced in the content model of an element (i.e. by means of a <classRef> element within the <content> of an <elementSpec>), its meaning will depend on the value of its *expand* attribute.

If this attribute is not specified, the <classRef> is interpreted to mean an alternated list of all the current members of the class named. For example, suppose that the members of the class `model.hiLike` are elements <hi>, `<it>`, and `<bo>`. Then a content model such as

```
<content>
  <classRef  key="model.hiLike"/>
</content>
```

would be equivalent to the explicit content model:

```
<content>
  <alternate>
    <elementRef  key="hi"/>
    <elementRef  key="it"/>
    <elementRef  key="bo"/>
  </alternate>
</content>
```

(or, to use RELAX NG compact syntax, `( hi | it | bo )`). However, a content model of `<classRef expand="sequence"/>` would be equivalent to the following explicit content model:

```
<content>
  <sequence>
    <elementRef  key="hi"/>
    <elementRef  key="it"/>
    <elementRef  key="bo"/>
  </sequence>
</content>
```

(or, in RELAX NG compact syntax, `( hi, it, bo )`).

An attribute class (a <classSpec> of *type* atts) contains an <attList> element which lists the attributes that all the members of that class inherit from it. For example, the class `att.interpLike` defines a small set of attributes common to all elements which are members of that class: those attributes are listed by the <attList> element

contained by the <classSpec> for `att.interpLike`. When processing the documentation elements for elements which are members of that class, an ODD processor is required to extend the <attList> (or equivalent) for such elements to include any attributes defined by the <classSpec> elements concerned. There is a single global attribute class, `att.global`, to which some modules contribute additional attributes when they are included in a schema.

23.7 Macro Specifications

The <macroSpec> element is used to declare and document predefined strings or patterns not otherwise documented by the elements described in this section. A corresponding <macroRef> element may be used to select a specific named pattern from those available. Patterns are used as a shorthand chiefly to describe common content models and datatypes, but may be used for any purpose. The following elements are used to represent patterns:

`<macroSpec>` (macro specification) documents the function and implementation of a pattern.

`<macroRef>` points to the specification for some pattern which is to be included in a schema.

- `@key` the identifier used for the required pattern within the source indicated.

23.8 Building a TEI Schema

The specification elements, and some of their children, are all members of the `att.identified` class, from which they inherit the following attributes:

`att.identified` provides identifying attributes for elements which can be subsequently referenced by means of a *key* attribute.

- `@ident` supplies the identifier by which this element may be referenced.
- `@predeclare` says whether this object should be predeclared in the `tei` infrastructure module.
- `@module` supplies a name for the module in which this object is to be declared.

This attribute class is a subclass of the `att.combinable` class from which it (and some other elements) inherits the following attribute:

`att.combinable` provides attributes indicating how multiple references to the same object in a schema should be combined.

- `@mode` specifies the effect of this declaration on its parent object.

This attribute class, in turn, is a subclass of the `att.deprecated` class, from which it inherits the following attribute:

`att.deprecated` provides attributes indicating how a deprecated feature will be treated in future releases.

- `@validUntil` provides a date before which the construct being defined will not be removed.

The *validUntil* attribute may be used to signal an intent to remove a construct from future versions of the schema being specified.

The <elementSpec>, <attDef> and <schemaSpec> specification elements also have an attribute which determines which namespace to which the object being created will belong. In the case of <schemaSpec>, this namespace is inherited by all the elements created in the schema, unless they have their own *ns*.

`att.namespaceable` provides attributes indicating the target namespace for an object being created.

These attributes are used by an ODD processor to determine how declarations are to be combined to form a schema or DTD, as further discussed in this section.

23.8.1 TEI customizations

As noted above, a TEI schema is defined by a <schemaSpec> element containing an arbitrary mixture of explicit declarations for objects (i.e. elements, classes, patterns, or macro specifications) and references to other objects containing such declarations (i.e. references to specification groups, or to modules). A major purpose of this mechanism is to simplify the process of defining user customizations, by providing a formal method for the user to combine new declarations with existing ones, or to modify particular parts of existing declarations.

In the simplest case, a user-defined schema might just combine all the declarations from two nominated modules:

```
<schemaSpec ident="example">
  <moduleRef key="core"/>
```

```
  <moduleRef  key="linking"/>
</schemaSpec>
```

An ODD processor, given such a document, should combine the declarations which belong to the named modules, and deliver the result as a schema of the requested type. It may also generate documentation for the elements declared by those modules. No source is specified for the modules, and the schema will therefore combine the declarations found in the most recent release version of the TEI Guidelines known to the ODD processor in use.

The value specified for the *source* attribute, when it is supplied as a URL, specifies any convenient location from which the relevant ODD files may be obtained. For the current release of the TEI Guidelines, a URL in the form `http://www.tei-c.org/Vault/P5/x.y.z/xml/tei/odd/p5subset.xml` may be used, where `x.y.z` represents the P5 version number, e.g. `1.3.0`. Alternatively, if the ODD files are locally installed, it may be more convenient to supply a value such as ../ODDs/p5subset.xml".

The value for the *source* attribute may be any form of URI. A set of TEI-conformant specifications in a form directly usable by an ODD processor must be available at the location indicated. When no *source* value is supplied, an ODD processor may either raise an error or assume that the location of the current release of the TEI Guidelines is intended.

If the source is specified in the form of a private URI, the form recommended is `aaa:x.y.z`, where `aaa` is a prefix indicating the markup language in use, and `x.y.z` indicates the version number. For example, `tei:1.2.1` should be used to reference release 1.2.1 of the current TEI Guidelines. When such a URI is used, it will usually be necessary to translate it before such a file can be used in blind interchange.

The effect of a <moduleRef> element is to include in the schema all declarations provided by that module. This may be modified by means of the attributes *include* and *except* which allow the encoder to supply an explicit lists of elements from the stated module which are to be included or excluded respectively. For example:

```
<schemaSpec  ident="example">
  <moduleRef  key="core"
    except="add del orig reg"/>
  <moduleRef  key="linking"
    include="linkGrp link"/>
</schemaSpec>
```

The schema specified here will include all the elements supplied by the core module except for <add>, <del>, <orig>, and <reg>. It will also include only the <linkGrp> and <link> elements from the linking module.

Alternatively, the element <elementRef> may be used to indicate explicitly which elements are to be included in a schema. The same effect as the preceding example might thus be achieved by the following:

```
<schemaSpec  ident="example">
  <moduleRef  key="core"
    except="add del orig reg"/>
  <elementRef  key="linkGrp"/>
  <elementRef  key="link"/>
</schemaSpec>
```

Note that in this last case, there is no need to specify the name of the module from which the two element declarations are to be found; in the TEI scheme, element names are unique across all modules. The module is simply a convenient way of grouping together a number of related declarations.

In the same way, a schema may select a subset of the attributes available in a specific class, using the <classRef> element to point to an attribute class:

```
<schemaSpec ident="example">
  <moduleRef key="tei"/>
<!-- ... -->
  <classRef key="att.global.linking"
    include="corresp"/>
<!-- ... -->
</schemaSpec>
```

Here, only the *corresp* attribute is included; the other attributes in the class are not available. The same effect can be achieved using *except*:

```
<schemaSpec ident="example">
  <moduleRef key="tei"/>
<!-- ... -->
  <classRef key="att.global.linking"
    except="copyOf exclude next prev sameAs select synch"/>
<!-- ... -->
</schemaSpec>
```

A schema may also include declarations for new elements, as in the following example:

```
<schemaSpec ident="example">
  <moduleRef key="header"/>
  <moduleRef key="verse"/>
  <elementSpec ident="soundClip">
    <classes>
      <memberOf key="model.pPart.data"/>
    </classes>
  </elementSpec>
</schemaSpec>
```

A declaration for the element `<soundClip>`, which is not defined in the TEI scheme, will be added to the output schema. This element will also be added to the existing TEI class `model.pPart.data`, and will thus be available in TEI conformant documents. Attributes from existing TEI classes could be added to the new element using <attRef>:

```
<schemaSpec ident="example">
  <moduleRef key="header"/>
  <moduleRef key="verse"/>
  <elementSpec ident="soundClip">
    <classes>
      <memberOf key="model.pPart.data"/>
    </classes>
    <attList>
      <attRef class="att.global.source"
        key="source"/>
    </attList>
  </elementSpec>
</schemaSpec>
```

This will provide the *source* attribute from the `att.global.source` class on the new `<soundClip>` element.

A schema might also include re-declarations of existing elements, as in the following example:

```
<schemaSpec ident="example">
  <moduleRef key="header"/>
  <moduleRef key="teistructure"/>
  <elementSpec ident="head" mode="change">
    <content>
      <macroRef key="macro.xtext"/>
    </content>
  </elementSpec>
</schemaSpec>
```

The effect of this is to redefine the content model for the element <head> as plain text, by over-riding the <content> child of the selected <elementSpec>. The attribute specification `mode="change"` has the effect of over-riding only those children elements of the <elementSpec> which appear both in the original specification and in the new specification supplied above: <content> in this example. Note that if the value for *mode* were replace, the effect would be to replace all children elements of the original specification with the children elements of the new specification, and thus (in this example) to delete all of them except <content>.

A schema may not contain more than two declarations for any given component. The value of the *mode* attribute is used to determine exactly how the second declaration (and its constituents) should be combined with the first. The following table summarizes how a processor should resolve duplicate declarations; the term *identifiable* refers to those elements which can have a *mode* attribute:

mode value	existing declaration	effect
add	no	add new declaration to schema; process its children in add mode
add	yes	raise error
replace	no	raise error
replace	yes	retain existing declaration; process new children in replace mode; ignore existing children
change	no	raise error
change	yes	process identifiable children according to their modes; process unidentifiable children in replace mode; retain existing children where no replacement or change is provided
delete	no	raise error
delete	yes	ignore existing declaration and its children

23.8.2 Combining TEI and Non-TEI Modules

In the simplest case, all that is needed to include a non-TEI module in a schema is to reference its RELAX NG source using the *url* attribute on <moduleRef>. The following specification, for example, creates a schema in which declarations from the non-TEI module `svg11.rng` (defining Standard Vector Graphics) are included. To avoid any risk of name clashes, the schema specifies that all TEI patterns generated should be prefixed by the string ”TEI_”.

```
<schemaSpec prefix="TEI_" ident="testsvg"
  start="TEI svg">
  <moduleRef key="header"/>
  <moduleRef key="core"/>
  <moduleRef key="tei"/>
  <moduleRef key="textstructure"/>
  <moduleRef url="svg11.rng"/>
</schemaSpec>
```

This specification generates a single schema which might be used to validate either a TEI document (with the root element <TEI>), or an SVG document (with a root element `<svg:svg>`), but would *not* validate a TEI document

containing <svg:svg> or other elements from the SVG language. For that to be possible, the <svg:svg> element must become a member of a TEI model class (*1.3. The TEI Class System*), so that it may be referenced by other TEI elements. To achieve this, we modify the last <moduleRef> in the above example as follows:

```
<moduleRef  url="svg11.rng">
  <content>
    <rng:define  name="TEI_model.graphicLike"
      combine="choice">
      <rng:ref  name="svg"/>
    </rng:define>
  </content>
</moduleRef>
```

This states that when the declarations from the svg11.rng module are combined with those from the other modules, the declaration for the model class model.graphicLike in the TEI module should be extended to include the element <svg:svg> as an alternative. This has the effect that elements in the TEI scheme which define their content model in terms of that element class (notably <figure>) can now include it. A RELAX NG schema generated from such a specification can be used to validate documents in which the TEI <figure> element contains any valid SVG representation of a graphic, embedded within an <svg:svg> element.

23.8.3 Linking Schemas to XML Documents

Schemas can be linked to XML documents by means of the <?xml-model?> processing instruction described in the W3C Working Group Note *Associating Schemas with XML documents* (https://www.w3.org/TR/xml-model/). <?xml-model?> can be used for any type of schema, and may be used for multiple schemas:

```
  <?xml-model href="tei_ tite.rng" type="application/xml" ?>
<?xml-model href="checkLinks.sch" type="application/xml" schematypens="http://purl.oclc.org/dsdl/
?>
<?xml-model href="tei_ tite.odd" type="application/tei+xml" schematypens="http://www.tei-c.org/ns
?>
```

This example includes a standard RELAX NG schema, a Schematron schema which might be used for checking that all pointing attributes point at existing targets, and also a link to the TEI ODD file from which the RELAX NG schema was generated. See also *2.3.10. The Schema Specification* for details of another method of linking an ODD specification into your file by including a <schemaSpec> element in <encodingDesc>.

23.9 Module for Documentation Elements

The module described in this chapter makes available the following components:

Module tagdocs: Documentation of TEI and other XML markup languages

- *Elements defined*: altIdent alternate anyElement att attDef attList attRef classRef classSpec classes code constraint constraintDecl constraintSpec content dataFacet dataRef dataSpec datatype defaultVal eg egXML elementRef elementSpec empty equiv exemplum gi ident interleave listRef macroRef macroSpec memberOf model modelGrp modelSequence moduleRef moduleSpec outputRendition param paramList paramSpec remarks schemaSpec sequence specDesc specGrp specGrpRef specList tag textNode val valDesc valItem valList
- *Classes defined*: att.combinable att.deprecated att.identified att.namespaceable att.predicate att.repeatable att.translatable model.contentPart

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema.*

The elements described in this chapter are all members of one of three classes: model.oddDecl, model.oddRef, or model.phrase.xml, with the exceptions of <schemaSpec> (a member of

`model.divPart`) and both <eg> and <egXML> (members of `model.common` and `model.egLike`). All of these classes are declared along with the other general TEI classes, in the basic structure module documented in *1. The TEI Infrastructure*.

In addition, some elements are members of the `att.identified` class, which is documented in *23.8.1. TEI customizations* above.

24 Using the TEI

This section discusses some technical topics concerning the deployment of the TEI markup schema documented elsewhere in these Guidelines. In section *24.3. Customization* we discuss the scope and variety of the TEI customization mechanisms. In *24.4. Conformance* we define the notions of *TEI Conformance* and *TEI Extension.* Since the ODD markup description language defined in chapter *23. Documentation Elements* is fundamental to the way conformance and customization are handled in the TEI system, these two definitional sections are followed by a section (*24.5. Implementation of an ODD System*) which describes the intended behaviour of an ODD processor.

24.1 Serving TEI files with the TEI Media Type

In February 2011, the media type `application/tei+xml` was registered with IANA for 'markup languages defined in accordance with the Text Encoding and Interchange guidelines' (RFC 6129). We recommend that any XML file whose root element is in the TEI namespace be served with the media type `application/tei+xml` to enable and encourage automated recognition and processing of TEI files by external applications.

24.2 Obtaining the TEI

As discussed in chapter *23. Documentation Elements*, all components of the TEI schema are generated from a single set of TEI XML source files. Schemas can be generated in each of XML DTD language, W3C schema language, and RELAX NG schema language. Documentation can be generated in a variety of commonly-used document formats, including HTML, DOCX, or PDF.

TEI components are freely available over the Internet and elsewhere. The canonical home for the TEI source, the schema fragments generated from it, and example modifications, is the TEI repository at `https://github.com/TEIC/TEI`; versions are also available in other formats, along with copies of these Guidelines and related materials, from the TEI web site at `http://www.tei-c.org/`.

24.3 Customization

These Guidelines provide an encoding schema suitable for encoding a very wide range of texts, and capable of supporting a wide variety of applications. For this reason, the TEI schema supports a variety of different approaches to solving similar problems, and also defines a much richer set of elements than is likely to be necessary in any given project. Furthermore, the TEI schema may be extended in well-defined and documented ways for texts that cannot be conveniently or appropriately encoded using what is provided. For these reasons, it is almost impossible to use the TEI schema without customizing it in some way.

This section describes how the TEI encoding schema may be customized, and should be read in conjunction with chapter *23. Documentation Elements*, which describes how a specific application of the TEI encoding schema should be documented. The documentation system described in that chapter is, like the rest of the TEI schema, independent of any particular schema or document type definition language.

Formally speaking, these Guidelines provide both syntactic rules about how elements and attributes may be used in valid documents and semantic recommendations about what interpretation should be attached to a given syntactic construct. In this sense, they provide both a *document type definition* and a *document type declaration.* More exactly, we may distinguish between the *TEI Abstract Model*, which defines a set of related concepts, and the *TEI schema* which defines a set of syntactic rules and constraints. Many (though not all) of the semantic recommendations are provided solely as informal descriptive prose, though some of them are also enforced by means of such constructs as datatypes (see *1.4.2. Datatype Specifications*), or by schema constraints expressed using the Schematron language. Schematron constraints provide information about special kinds of validation errors dependent on conditional relationships, such as the invalidity of an attribute name or value on one element when another is present, or when, given a pair of attributes such as *minOccurs* and *maxOccurs*, the minimum value exceeds the maximum value. Schematron constraints also provide warnings when a particular element, attribute, or combination is to be deprecated in future releases of the TEI scheme, to alert users that the feature in question is no longer to be used after a certain date. Very rarely, TEI Schematron constraints offer warnings that do not explicitly break with the TEI but suggest a more efficient or less ambiguous encoding. Although the descriptions, validation errors, and warnings have been written with care, there will inevitably be cases where the intention of the contributors has not been conveyed with sufficient clarity to prevent users of these Guidelines from 'extending' them in the sense of attaching slightly variant semantics to them.

Beyond this unintentional semantic extension, some of the elements described can intentionally be used in a variety of ways; for example, the element <note> has an attribute *type* which can take on arbitrary string values, depending on how it is used in a document. A new type of 'note', therefore, requires no change in the existing model. On the other hand, for many applications, it may be desirable to constrain the possible values for the *type* attribute to a small set of possibilities. A schema modified in this way would no longer necessarily regard as valid the same set of documents as the corresponding unmodified TEI schema, but would remain faithful to the same conceptual model.

This section explains how the TEI schema can be customized by suppressing elements, modifying classes of elements, or adding elements. Documents which validate against an application of the TEI schema which has been customized in this way may or may not be considered 'TEI-conformant', as further discussed in section *24.4. Conformance*.

The TEI system is designed to support modification and customization in a documented way that can be validated by an XML processor. This is achieved by writing a small TEI-conformant document, known informally as an ODD (One Document Does it all), from which an appropriate processor can generate both human-readable documentation, and a schema expressed in a language such as RELAX NG or DTD. The mechanisms used to instantiate a TEI schema differ for different schema languages, and are therefore not defined here. In XML DTDs, for example, extensive use is made of parameter entities, while in RELAX NG schemas, extensive use is made of patterns. In either case, the names of elements and, wherever possible, their attributes and content models are defined indirectly. The syntax used to implement this indirection also varies with the schema language used, but the underlying constructs in the TEI Abstract Model are given the same names. This indirection makes it simpler to implement customization of the TEI system in an accessible and human-readable way.

As further discussed in section *1. The TEI Infrastructure*, the TEI encoding schema comprises a set of class and macro declarations, and a number of *modules*. Each module is made up of element and attribute declarations, and a schema is made by combining a particular set of modules together. In the absence of any other kind of customization, when modules are combined together:

1. all the elements defined by the module (and described in the corresponding section of these Guidelines) are included in the schema;
2. each such element is identified by the canonical name given it in these Guidelines;
3. the content model of each such element is as defined by these Guidelines;
4. the names, datatypes, and permitted values declared for each attribute associated with each such element are as given in these Guidelines;
5. the elements comprising element classes and the meaning of macro declarations expressed in terms of element classes is determined by the particular combination of modules selected.

The TEI customization mechanisms allow the user to control this behaviour as follows:

1. particular elements may be suppressed, removing them from any classes in which they are members, and also from any generated schema;
2. new elements may be added to an existing class, thus making them available in macros or content models defined in terms of those classes;
3. additional attributes, or attribute values, may be specified for an individual element or for classes of elements;
4. within certain limits, attributes, or attribute values, may also be removed either from an individual element or for classes of elements;
5. the characteristics inherited by one class from another class may be modified by modifying its class membership: all members of the class then inherit the changed characteristics;
6. the set of values legal for an attribute or attribute class may be constrained or relaxed by supplying or modifying a value list, or by modifying its datatype.
7. within certain limits, the name (generic identifier) associated with an element may be changed, without changing the semantic or syntactic properties of the element;

The modification mechanisms presented in this section are quite general, and may be used to make all the types of changes just listed.

The recommended way of implementing and documenting all such modifications is by means of the ODD system described in chapter *23. Documentation Elements*; in the remainder of this section we give specific examples to illustrate how that system may be applied. An ODD processor, such as the Roma application supported by the TEI, or any other comparable set of stylesheets will use the declarations provided by an ODD to generate appropriate sets of declarations in a specific schema language such as RELAX NG or the XML DTD language. We do not discuss in detail here how this should be done, since the details are schema language-specific; some background information about the methods used for XML DTD and RELAX NG schema generation is however provided in section *1.2. Defining a TEI Schema*. Several example ODD files are also provided as part of the standard TEI release: see further section *24.3.4. Examples of Modification* below.

24.3.1 Kinds of Modification

For ease of discussion, we distinguish the following different kinds of modification:

1. deletion of elements;
2. modification of content models;
3. modification of attribute and attribute-value lists;
4. modification of class membership;
5. addition of new elements.
6. renaming of elements;

Each of these is described in the following sections.

Each kind of modification changes the set of documents that will be considered valid according to the resulting schema. A schema derived from any combination of unmodified TEI declarations (an "unmodified schema") may be thought of as defining a certain set of documents. A schema deriving from a combination of modified TEI declarations (a "modified schema") will define a different set of documents. The set of documents valid according to the modified schema may or may not be properly contained by the set of documents considered to be valid according to the unmodified schema. The schema `TEI-All` is the special case of the unmodified schema which includes all currently available TEI modules. We use the term *clean modification* for cases where the set of documents defined by a modified schema is a proper subset of the set of documents defined by TEI-All. Where this is not the case, that is, where the modified schema considers valid some documents which TEI-All does not, we use the term *unclean modification*. Despite this terminology, unclean modifications are not particularly deprecated, and their use may often be vital to the success of a project. The concept is introduced solely to distinguish the effects of different kinds of modification.

24.3.1.1 Deletion of Elements

The simplest way to modify the supplied modules is to suppress one or more of the supplied elements. This is simply done by setting the *mode* attribute to delete on an <elementSpec> for the element concerned.

For example, if the <note> element is not to be used in a particular application, but has been included via one of the supplied modules, then the schema specification concerned will contain a declaration like the following:

```
<elementSpec  ident="note"  mode="delete"/>
```

The *ident* attribute here supplies the canonical name of the element to be deleted and the *mode* attribute specifies what is to be done with it. There is no need to specify the module concerned, since element names are unique across all TEI modules. The full specification for a schema in which this modification is applied would thus be something like the following:

```
<schemaSpec  ident="mySchema">
  <moduleRef  key="core"/>
<!-- other modules used by this customization -->
  <elementSpec  ident="note"  mode="delete"/>
</schemaSpec>
```

In most cases, deletion is a clean modification, since most elements are optional. Documents that are valid with respect to the modified schema are also valid according to TEI-All. To say this another way, the set of documents matching the new schema is contained by the set of documents matching the original schema.

There are however some elements in the TEI schema which have mandatory children; for example, the element <listPerson> must contain at least one element from the `model.personLike` class. If that class has no members because all of its member elements have been removed, then the content model cannot be satisfied. A modification which keeps <listPerson> but removes all of its possible children would therefore be regarded as unclean. So long as at least one member of the class remains available, however, deleting other members would not have this effect, and would therefore be regarded as a clean modification.

In general, whenever the element deleted by a modification is mandatory within the content model of some other (undeleted) element, the result is an unclean modification, and may also break the TEI Abstract Model (*24.4.3. Conformance to the TEI Abstract Model*). However, the parent of a mandatory child can be safely removed if it is itself optional.

To determine whether or not an element is mandatory in a given context, the user must inspect the content model of the element concerned. In most cases, content models are expressed in terms of model classes rather than elements; hence, removing an element will generally be a clean modification, since there will generally be other members of the class available. If a class is completely depopulated by a modification, then the cleanliness of the modification will depend upon whether or not the class reference is mandatory or optional, in the same way as for an individual element.

24.3.1.2 Modification of Content Models

The content model for an element in the TEI schema is defined by means of a <content> element within the <elementSpec> which specifies it. For example, the specification for the element <term> provided by these Guidelines contains a <content> element like the following:

```
<content>
  <macroRef  key="macro.phraseSeq"/>
</content>
```

This content model consists of a reference to a macro called `macro.phraseSeq`. Further examination shows that this macro in turn expands to an optional repeatable alternation of text (<textNode>) with references to three other classes (`model.gLike`, `model.phrase`, or `model.global`). For some particular application it might be preferable to insist that <term> elements should only contain plain text, excluding these other possibilities.[135] This could be achieved simply by supplying a specification for <term> like the following:

```
<elementSpec  ident="term"  module="core"
  mode="change">
  <content>
    <textNode/>
  </content>
</elementSpec>
```

This is a clean modification which does not change the meaning of a TEI element; there is therefore no need to assign the element to some other namespace than that of the TEI, though it may be considered good practice; see further *24.3.2. Modification and Namespaces* below.

A change of this kind, which simplifies the possible content of an element by reducing its model to one of its existing components, is always clean, because the set of documents matched by the resulting schema is a subset of the set of documents which would have been matched by TEI-All.

Note that content models are generally defined (as far as possible) in terms of references to model classes, rather than to explicit elements. This means that the need to modify content models is greatly reduced: if an element is deleted or modified, for example, then the deletion or modification will be available for every content model which

[135] Excluding `model.gLike` is generally inadvisable however, since without it the resulting schema has no way of referencing non-Unicode characters.

references that element via its class, as well as those which reference it explicitly. For this reason it is not (in general) good practice to replace class references by explicit element references, since this may have unintended side effects.

An unqualified reference to an element class within a content model generates a content model which is equivalent to an alternation of all the members of the class referenced. Thus, a content model which refers to the model class `model.phrase` will generate a content model in which any one of the members of that class is equally acceptable. The <classRef> element used to reference a class has an *expand* attribute which may be used to vary this behaviour, for example to require 'an optional repeatable alternation of all members of a class', 'a sequence containing no more than one of each member of the class', etc. as described further in *23.6. Class Specifications*.

Content model changes which are not simple restrictions on an existing model should be undertaken with caution. The set of documents matching the schema which results from such changes is unlikely to be contained by the set of documents matching TEI-All, and such changes are therefore regarded as unclean. When content models are changed or extended, care should be taken to respect the existing semantics of the element concerned as stated in these Guidelines. For example, the element <l> is defined as containing a line of verse. It would not therefore make sense to redefine its content model so that it could also include members of the class `model.pLike` such as <p> or <ab>. Although syntactically feasible, such a modification would not be regarded as TEI-conformant because it breaks the TEI Abstract Model.

24.3.1.3 Modification of Attribute and Attribute Value Lists

The attributes applicable to a given element may be specified in two ways: they may be given explicitly, by means of an <attList> element within the corresponding <elementSpec>, or they may be inherited from an attribute class, as specified in the <classes> element. To add a new attribute to an element, the designer should therefore first check to see whether this attribute is already available from some existing attribute class. If it is, then the simplest method of adding it will be to make the element in question a member of that class, as further discussed below. If this is not possible, then a new <attDef> element must be added to the existing <attList> for the element in question.

Whichever method is adopted, the modification capabilities are the same as those available for elements. Attributes may be added or deleted from the list, using the *mode* attribute on <attDef> in the same way as on <elementSpec>. The 'content' of an attribute is defined by means of the <datatype>, <valList>, or <valDesc> elements within the <attDef> element. Any of these elements may be changed.

Suppose, for example, that we wish to add two attributes to the <eg> element (used to indicate examples in a text), *type* to characterize the example in some way, and *valid* to indicate whether the example is considered valid or not. A quick glance through the Guidelines indicates that the attribute class `att.typed` could be used to provide the *type* attribute, but there is no comparable class which will provide a *valid* attribute. The existing <eg> element in fact has no local attributes defined for it at all: we will therefore need to add not only an <attDef> element to define the new attribute, but also an <attList> to hold it.

We begin by adding the new *valid* attribute:

```
<elementSpec ident="eg" module="tagdocs"
  mode="change">
  <attList>
    <attDef ident="valid" mode="add"
      ns="http://www.example.com/ns/nonTEI">
      <desc>indicates whether or not the example is considered to be valid</desc>
      <datatype>
        <dataRef key="teidata.truthValue"/>
      </datatype>
    </attDef>
  </attList>
</elementSpec>
```

The value supplied for the *mode* attribute on the <attDef> element is add; if this attribute already existed on the element we are modifying this should generate an error, since a specification cannot have more than one attribute of the same name. If the attribute is already present, we can replace the whole of the existing declaration by supplying replace as the value for *mode*; alternatively, we can change some parts of an existing declaration only by supplying just the new parts, and setting change as the value for *mode*.

Because the new attribute is not defined by the TEI, it is good practice to specify a namespace for it on the <attDef>; see further *24.3.2. Modification and Namespaces*.

As noted above, adding the new *type* attribute involves changing this element's class membership; we therefore discuss that in the next section (*24.3.1.4. Class Modification*).

The canonical name for the new attribute is *valid*, and is supplied on the *ident* attribute of the <attDef> element. In this simple example, we supply only a description and datatype for the new attribute; the former is given by the <desc> element, and the latter by the <datatype> element. (There are of course many other pieces of information which could be supplied, as documented in *23. Documentation Elements*). The content of the <datatype> element is a <dataRef> element which references an existing TEI data specification.

It is often desirable to constrain the possible values for an attribute to a greater extent than is possible by simply supplying a TEI datatype for it. This facility is provided by the <valList> element, which can also appear as a child of the <attDef> element. Suppose for example that, rather than simply indicating whether or not the example is considered valid by means of the values true and false we wish to provide a more nuanced indication, using encoded values such as A, B, and C. A declaration like the following might be appropriate:

```
<elementSpec ident="eg" module="tagdocs"
  mode="change">
  <attList>
    <attDef ident="valid"
      ns="http://www.example.com/ns/nonTEI" mode="add">
      <desc>indicates the validity of the example by supplying one of three predefined
            codes for it.</desc>
      <datatype>
        <dataRef key="teidata.enumerated"/>
      </datatype>
      <valList type="closed">
        <valItem ident="A">
          <desc>validity is of the highest class</desc>
        </valItem>
        <valItem ident="B">
          <desc>validity is of the second highest class</desc>
        </valItem>
        <valItem ident="C">
          <desc>validity is of the lowest class</desc>
        </valItem>
      </valList>
    </attDef>
  </attList>
</elementSpec>
```

The same technique may be used to replace or extend the <valList> supplied as part of any attribute in the TEI schema.

24.3.1.4 Class Modification

The concept of element classes was introduced in *1.3.2. Model Classes*; an understanding of it is fundamental to successful use of the TEI system. As noted there, we distinguish *model classes*, the members of which all have structural similarity, from *attribute classes*, the members of which simply share a set of attributes.

The part of an element specification which determines its class membership is an element called <classes>. All classes to which the element belongs must be specified within this, using a <memberOf> element for each.

To add an element to a class in which it is not already a member, all that is needed is to supply a new <memberOf> element within the <classes> element for the element concerned. For example, to add an element to the `att.typed` class, we include a declaration like the following:

```
<elementSpec ident="eg" module="tagdocs"
  mode="change" ns="http://www.example.com/ns/nonTEI">
```

```
  <classes  mode="change">
    <memberOf  key="att.typed"/>
  </classes>
</elementSpec>
```

Any existing class memberships for the element being changed are not affected because the *mode* attribute of the <classes> element is set to change (rather than its default value of replace). Consequently, in this case, the <eg> element retains its membership of the two classes (`model.common` and `model.graphicLike`) to which it already belongs.

Equally, to remove the attributes which an element inherits from its membership in some class, all that is needed is to remove the relevant <memberOf> element. For example, the element <term> defined in the core module is a member of two attribute classes, `att.typed` and `att.declaring`. It inherits the attributes *type* and *subtype* from the former, and the attribute *decls* from the latter. To remove the last of these attributes from this element, we need to remove it from that class:

```
<elementSpec  ident="term"  module="core"
  mode="change">
  <classes  mode="change">
    <memberOf  key="att.declaring"
      mode="delete"/>
  </classes>
</elementSpec>
```

If the intention is to change the class membership of an element completely, rather than simply add or remove it to or from one or more classes, the value of the *mode* attribute of <classes> can be set to replace (which is the default if no value is specified), indicating that the memberships indicated by its child <memberOf> elements are the only ones applicable. Thus the following declaration:

```
<elementSpec  ident="term"  module="core"
  mode="change"  ns="http://www.example.com/ns/nonTEI">
  <classes  mode="replace">
    <memberOf  key="att.interpLike"/>
  </classes>
</elementSpec>
```

would have the effect of removing the element <term> from both its existing attribute classes, and adding it to the `att.interpLike` class.

If however the *mode* attribute is set to change, the implication is that the memberships indicated by its child <memberOf> elements are to be combined with the existing memberships for the element.

To change or remove attributes inherited from an attribute class for all members of the class (as opposed to specific members of that class), it is also possible to modify the class specification itself. For example, the class `att.global.rendition` defines several attributes which are available for all elements, namely *rend*, *style*, and *rendition*. If we decide that we never wish to use the *rend* attribute, the simplest way of removing it is to supply a modified class specification for `att.global.rendition` as follows:

```
<classSpec  ident="att.global.rendition"
  type="atts"  mode="change">
  <attList>
    <attDef  ident="rend"  mode="delete"/>
  </attList>
</classSpec>
```

Because the *mode* attribute on the <classSpec> defining the attributes inherited through membership of this class has the value change, any of its existing identifiable components not specified in the modification above will remain unchanged. The only effect will therefore be to delete the *rend* attribute from the class, and hence from all elements which are members of the class.

The classes used in the TEI schema are further discussed in chapter *1. The TEI Infrastructure.* Note in particular that classes are themselves classified: the attributes inherited by a member of attribute class A may come to it directly from that class, or from another class of which A is itself a member. For example, the class `att.global` is itself a member of the classes `att.global.linking` and `att.global.analytic`. By default, these two classes are predefined as empty. However, if (for example) the `linking` module is included in a schema, a number of attributes (*corresp*, *sameAs*, etc.) are defined as members of the `att.global.linking` class. All elements which are members of `att.global` will then inherit these new attributes (see further section *1.3.1. Attribute Classes*). A new attribute may thus be added to the global class in two ways: either by adding it to the <attList> defined within the class specification for `att.global`; or by defining a new attribute class, and changing the class membership of the `att.global` class to reference it.

Such global changes should be undertaken with caution: in general removing existing non-mandatory attributes from a class will always be a clean modification, in the same way as removing non-mandatory elements. Adding a new attribute to a class however can be a clean modification only if the new attribute is labelled as belonging to some namespace other than the TEI.

The same mechanisms are available for modification of model classes. Care should be taken when modifying the model class membership of existing elements since model class membership is what determines the content model of most elements in the TEI schema, and a small change may have unintended consequences.

24.3.1.5 Addition of New Elements

To add a completely new element into a schema involves providing a complete element specification for it. It is recommended that the <classes> element of this new declaration should include a reference to at least one TEI model class. Without such a reference, the new element would not otherwise be referenced by the content model of any other TEI element, and would therefore be inaccessible within a TEI document. It is also possible to modify the content models of one or more existing elements to refer to the new element explicitly, as discussed in *24.3.1.2. Modification of Content Models* but this will generally be less convenient.

For example, the three elements <bibl>, <biblFull>, and <biblStruct> are all defined as members of the class `model.biblLike`. To add a fourth member (say `<myBibl>`) to this class, we need to include in the <elementSpec> defining our new element a <memberOf> element which nominates the intended class:

```
<elementSpec ident="myBibl" mode="add"
  ns="http://www.example.com/ns/nonTEI">
  <classes>
    <memberOf key="model.biblLike"/>
  </classes>
<!-- other parts of the new declaration here -->
</elementSpec>
```

The other parts of this declaration will typically include a description for the new element and information about its content model, its attributes, etc., as further described in *23. Documentation Elements*.

24.3.1.6 Renaming of Elements

Every element and other named markup construct in the TEI schema has a *canonical name*, usually composed of English language words or syllables: this name is supplied as the value of the *ident* attribute on the <elementSpec>, <attDef>, <classSpec>, or <macroSpec> used to define it. In some circumstances, it may be convenient for the element or attribute declaration used within a schema generated from that specification to take a different form, for example, permitting schemas to use generic identifiers from a different language, or in an abbreviated form. There may be many alternative identifiers for the same markup construct, and an ODD processor may choose which of them to use for a given purpose. Each such alternative name is supplied by means of an <altIdent> element within the specification element concerned.

For example, the following declaration converts <note> to `<nt>`:

```
<elementSpec ident="note" module="core"
  mode="change">
  <altIdent>nt</altIdent>
</elementSpec>
```

Note that the *mode* attribute on the <elementSpec> now takes the value change to indicate that those parts of the element specification not supplied are to be inherited from the standard definition. The content of the <altIdent> element is now available for use in place of the canonical *ident* value in the schema generated.

Renaming in this way is is an inherently unclean modification (because the set of documents matched by the resulting schema is not contained by the set matched by TEI-All), even though the process of converting any document in which elements have been renamed into an exactly equivalent document using canonical names is completely deterministic. Documents using such a schema should not claim to be in the TEI namespace, but either use a null namespace or some user-defined namespace, as further discussed in *24.3.2. Modification and Namespaces*; this is necessary to avoid the risk of name collision between the new name and all existing TEI names as well as for reasons of conformance (see further *24.3. Customization*).

24.3.2 Modification and Namespaces

All the elements defined by the TEI schema are labelled as belonging to a single *namespace*, maintained by the TEI and with the URI http://www.tei-c.org/ns/1.0.[136] Only elements which are unmodified or which have undergone a clean modification may use this namespace. Note however that TEI-defined attributes are not associated with any namespace.

This implies that any other modification must either specify a different namespace or, equivalently, specify no namespace at all. The *ns* attribute is provided on elements <schemaSpec>, <elementSpec>, and <attDef> for this purpose.

Suppose, for example, that we wish to add a new attribute *topic* to the existing TEI element <p>. In the absence of namespace considerations, this would be an unclean modification, since <p> does not currently have such an attribute. The most appropriate action is to explicitly attach the new attribute to a new namespace by a declaration such as the following:

```
<elementSpec ident="p" mode="change">
  <attList>
    <attDef ident="topic" mode="add"
      ns="http://www.example.org/ns/nonTEI">
      <desc>indicates the topic of a TEI paragraph</desc>
      <datatype>
        <dataRef key="teidata.word"/>
      </datatype>
    </attDef>
  </attList>
</elementSpec>
```

Document instances using a schema derived from this ODD can now indicate clearly the status of this attribute:

```
<div
   xmlns:my="http://www.example.org/ns/nonTEI">
<!-- ... -->
  <p n="12" my:topic="rabbits">Flopsy, Mopsy, Cottontail, and Peter...</p>
</div>
```

[136] This is not strictly the case, since the element <egXML> used to represent TEI examples has its own namespace, http://www.tei-c.org/ns/Examples; this is the only exception however.

Since *topic* is explicitly labelled as belonging to something other than the TEI namespace, we regard the modification which introduced it as clean. A namespace-aware processor will be able to validate those elements in the TEI namespace against the unmodified schema.[137]

Similar considerations apply when modification is made to the content model or some other aspect of an element, or when a new element is declared. All such changes should be explicitly labelled as belonging to some non-TEI namespace or to no namespace at all.

If the *ns* attribute is supplied on a <schemaSpec> element, it identifies the namespace applicable to all components of the schema being specified. Even if such a schema includes unmodified modules from the TEI namespace, the elements contained by such modules will now be regarded as belonging to the namespace specified on the <schemaSpec>. This can be useful if it is desired simply to avoid namespace processing. For example, the following schema specification results in a schema called `noName` which has no namespace, even though it comprises declarations from the TEI `header` module:

```
<schemaSpec ns="" ident="noName">
  <moduleRef key="header"/>
<!-- ... -->
</schemaSpec>
```

When a customization introduces new elements, and therefore one or more new namespaces, users may want to consider redefining *defaultExceptions* on <schemaSpec> such that the new namespace or namespaces are included. This is because elements matched by <anyElement> (e.g. the one used as the content of <xenoData>) must exclude any element that may carry an ID-type attribute (generally *xml:id*). This is particularly important if the target schema language is RELAX NG and one wishes to enable ID/IDREF/IDREFS compatibility mode: not adding the new namespaces to *defaultExceptions* will result in 'conflicting ID-types' errors.

```
<schemaSpec ns="http://www.example.org/ns/nonTEI"
  ident="example"
  defaultExceptions="http://www.example.org/ns/nonTEI http://www.tei-c.org/ns/1.0
http://www.tei-c.org/ns/Examples">
<!-- ... -->
</schemaSpec>
```

In addition to the TEI canonical namespace mentioned above, the TEI may also define namespaces for approved translations of the TEI schema into other languages. The namespace for such translations is the same as that for the canonical namespace, suffixed by the appropriate ISO language identifier (*vi.1 Language Identification*). A schema specification using the Chinese translation, for example, would use the namespace `http://www.tei-c.org/ns/1.0/zh`

24.3.3 Documenting the Modification

The elements used to define a TEI customization (<schemaSpec>, <moduleRef>, <elementSpec>, etc.) will typically be used within a TEI document which supplies further information about the intended use of the new schema, the meaning and application of any new or modified elements within it, and so on. This document will typically conform to a schema which includes components from the module described in chapter *23. Documentation Elements*.[138]

Where the customization to be documented simply consists in a selection of TEI modules, perhaps with some deletion of unwanted elements or attributes, the documentation need not specify anything further. Even here however it may be considered worthwhile to replace some of the semantic information provided by the unmodified TEI specification. For example, the <desc> element of an unmodified TEI <elementSpec> may describe an element in terms more general than appropriate to a particular project, or the <exemplum> elements within it may not illustrate the project's actual intended usage of the element, or the <remarks> element may contain discussions of

[137] Full namespace support does not exist in the DTD language, and therefore these techniques are available only to users of more modern schema languages such as RELAX NG or W3C Schema.

[138] This module can be used to document any XML schema, and has indeed been used to document several non-TEI schemas.

matters irrelevant to the project. These elements may therefore be replaced or deleted within an <elementSpec> as necessary.

Radical revision is also possible. It is feasible to produce a modification in which the <teiHeader> or <text> elements are not required, or in which any other rule stated in these Guidelines is either not enforced or not enforceable. In fact, the mechanism, if used in an extreme way, permits replacement of all that the TEI has to say about every component of its schema. Such revisions would result in documents that are not TEI-conformant in even the broadest sense, and it is not intended that encoders use the mechanism in this way. We discuss exactly what is meant by the concept of *TEI conformance* in the next section, *24.4. Conformance*.

24.3.4 Examples of Modification

Several examples of customizations of the TEI are provided as part of the standard release. They include the following:

tei_bare The schema generated from this customization is the minimum needed for TEI Conformance. It provides only a handful of elements.

tei_all The schema generated from this customization combines all available TEI modules, providing 588 elements.

tei_allPlus The schema generated from this customization combines all available TEI modules with three other non-TEI vocabularies, specifically MathML, SVG, and XInclude.

It is unlikely that any project would wish to use any of these extremes unchanged. However, they form a useful starting point for customization, whether by removing modules from tei_all or tei_allPlus, or by replacing elements deleted from tei_bare. They also demonstrate how an ODD document may be constructed to provide a basic reference manual to accompany schemas generated from it.

Shortly after publication of the first edition of these Guidelines, as a demonstration of how the TEI encoding schema might be adopted to meet 90% of the needs of 90% of the TEI user community, the TEI editors produced a brief tutorial defining one specific 'clean' modification of the TEI schema, which they called TEI Lite. This tutorial and its associated DTD became very popular and remain available in the TEI P5 Vault at `https://tei-c.org/Vault/P4/Lite/`. The lastest version of the tutorial and associated schema specification is included as one of the exemplars provided with TEI P5 and is available from the TEI web site at `https://tei-c.org/guidelines/customization/`.

An updated and expanded version of this schema known as `TEI simplePrint` was added to the Exemplars at release 3.1.0. The elements it defines have been modified to take advantage of the 'processing model' features (see further *23.5.4. Processing Models*) introduced to the Guidelines at release 3.0.0.

The exemplars provided with TEI P5 also include a customization file from which a schema for the validation of other customization files may be generated. This ODD, called tei_odds, combines the four basic modules with the tagdocs, dictionaries, gaiji, linking, and figures modules and also provides facilities for including RELAX NG or Schematron code within a document.

24.4 Conformance

The notion of *TEI Conformance* is intended to assist in the description of the format and contents of a particular XML document instance or set of documents. It may be found useful in such situations as:

- interchange or integration of documents amongst different researchers or users;
- software specifications for TEI-aware processing tools;
- agreements for the deposit of texts in, and distribution of texts from, archives;
- specifying the form of documents to be produced by or for a given project.

It is not intended to provide any other evaluation, for example of scholarly merit, intellectual integrity, or value for money. A document may be of major intellectual importance and yet not be TEI-conformant; a TEI-conformant document may be of no scholarly value whatsoever.

In this section we explore several aspects of conformance, and in particular attempt to define how the term *TEI-conformant* should be used. The terminology defined here should be considered normative: users and implementors of the TEI Guidelines should use the phrases 'TEI-conformant' and 'TEI Extension' only in the senses given and with the usages described.

A document is *TEI-conformant* if it:

- is a well-formed XML document (*24.4.1. Well-formedness Criterion*)
- can be validated against a *TEI Schema*, that is, a schema derived from the TEI Guidelines (*24.4.2. Validation Constraint*)
- conforms to the TEI Abstract Model (*24.4.3. Conformance to the TEI Abstract Model*)
- uses the *TEI namespace* (and other namespaces where relevant) correctly (*24.4.4. Use of the TEI Namespace*)
- is documented by means of a TEI-conformant *ODD file* (*24.4.5. Documentation Constraint*) which refers to the TEI Guidelines

Each of these criteria is discussed in more detail below.

A document is said to use a *TEI Extension* if it is a well-formed XML document which is valid against a TEI Schema which contains additional distinctions, representing concepts not present in the TEI Abstract Model, and therefore not documented in these Guidelines. Such a document cannot necessarily be transformed automatically to a TEI-conformant document without loss of information. However, since one of the goals of the TEI is to support extensions and modifications, it should not be assumed that no TEI document can include extensions: an extension which is expressed by means of the recommended mechanisms is also a TEI-conformant document provided that those parts of it which are not extensions are TEI-conformant.

A TEI-conformant document is said to follow *TEI Recommended Practice* if, wherever these Guidelines prefer one encoding practice to another, the preferred practice is used.

24.4.1 Well-formedness Criterion

These Guidelines mandate the use of well-formed XML as representation format. Documents must conform to the World Wide Web Consortium recommendation of the *Extensible Markup Language (XML) 1.0 (Fourth Edition)* or successor editions found at `https://www.w3.org/TR/xml/`. Other ways of representing the concepts of the TEI Abstract Model are possible, and other representations may be considered appropriate for use in particular situations (for example, for data capture, or project-internal processing). But such alternative representations should not be considered in any way TEI-conformant.

Previous versions of these Guidelines used SGML as a representation format. With the release of P5, the only representation format supported by these Guidelines became valid XML; legacy documents in SGML format should therefore be converted using appropriate software.

A TEI-conformant document must use the TEI namespace, and therefore must also include an XML-conformant namespace declaration, as defined below (*24.4.4. Use of the TEI Namespace*).

The use of XML greatly reduces the need to consider hardware or software differences between processing environments when exchanging data. No special packing or interchange format is required for an XML document, beyond that defined by the W3C recommendations, and no special 'interchange' format is therefore proposed by these Guidelines. For discussion of encoding issues that may arise in the processing of special character sets or non-standard writing systems, see further chapter *vi Languages and Character Sets*.

In addition to the well-formedness criterion, the W3C defines the notion of a *valid* document, as being a well-formed document which matches a specific set of rules or syntactic constraints, defined by a *schema*. As noted above, TEI conformance implies that the schema used to determine validity of a given document should be derived from the present Guidelines, by means of an ODD which references and documents components which these Guidelines define.

24.4.2 Validation Constraint

All *TEI-conformant* documents must validate against a schema file that has been derived from the published TEI Guidelines, combined and documented in the manner described in section *24.3. Customization*. We call the formal output of this process a *TEI Schema*.

The TEI does not mandate use of any particular schema language, only that this schema[139] should have been generated from a *TEI ODD file* that references the TEI Guidelines. Currently available tools permit the expression of schemas in any or all of the XML DTD language, W3C XML Schema, and RELAX NG (both compact and XML formats). Some of what is syntactically possible using the ODD formalism cannot be represented by all schema languages; and there are some features of some schema languages which have no counterpart in ODD. No single

[139]Here and elsewhere we use the word *schema* to refer to any formal document grammar language, irrespective of the formalism used to represent it.

schema language fully captures all the constraints implied by conformance to the TEI Abstract Model. A document which is valid according to a TEI schema represented using one schema language may not be valid against the same schema expressed in other languages; for example, the DTD language does not support namespaces.

As noted in section *24.3. Customization*, many varieties of TEI schema are possible and not all of them are necessarily *TEI-conformant*; derivation from an ODD is a necessary but not a sufficient condition for TEI Conformance.

24.4.3 Conformance to the TEI Abstract Model

The *TEI Abstract Model* is the conceptual schema instantiated by the TEI Guidelines. These Guidelines define, both formally and informally, a set of abstract concepts such as 'paragraph' or 'heading', and their structural relationships, for example stating that 'paragraph's do not contain 'heading's. These Guidelines also define classes of elements, which have both semantic and structural properties in common. Those semantic and structural properties are also a part of the TEI Abstract Model; the class membership of an existing TEI element cannot therefore be changed without changing the model. Elements can however be removed from a class by deletion, and new non-TEI elements within their own namespaces can be added to existing TEI classes.

24.4.3.1 Semantic Constraints

It is an important condition of TEI conformance that elements defined in the TEI Guidelines as having one specific meaning should not be used with another. For example, the element <l> is defined in the TEI Guidelines as containing a line of verse. A schema in which it is redefined to mean a typographic line, or an ordered queue of objects of some kind, cannot therefore be TEI-conformant, whatever its other properties.

The semantics of elements defined in the TEI Guidelines are conveyed in a number of ways, ranging from formally verifiable datatypes to informal descriptive prose. In addition, a mapping between TEI elements and concepts in other conceptual models may be provided by the <equiv> element where this is available.

A schema which shares equivalent concepts to those of the TEI conceptual model may be mappable to the TEI Schema by means of such a mechanism. For example, the concept of paragraph expressed in the TEI schema by the <p> element is probably the same concept as that expressed in the DocBook schema by the `<para>` element. Such areas of overlap facilitate interchange because elements from one namespace may be readily integrated with those from another, but do not affect the definition of conformance.

A document is said to conform to the *TEI Abstract Model* if features for which an encoding is proposed by the TEI Guidelines are encoded within it using the markup and other syntactic properties defined by means of a valid *TEI-conformant* schema. Hence, even though the names of elements or attributes may vary, a TEI-conformant document must respect the TEI Semantic Model, and be valid with respect to a TEI-conformant Schema. Although it may be possible to transform a document which follows the *TEI Abstract Model* into a *TEI-conformant* document, such a document is not itself conformant.

As noted above, the notion of semantic conformance cannot be completely enforced in a formal way. The TEI conceptual model is expressed by means of formal specification in a customization file, by means of descriptive prose in the body of these Guidelines, and implicitly by examples of usage. Any inconsistency between, for example, the text of these Guidelines and a part of a specification should be considered an error and reported to the TEI Council for correction.

24.4.3.2 Mandatory Components of a TEI Document

It is a long-standing requirement for any *TEI-conformant* document that it should contain a <teiHeader> element. To be more specific a *TEI-conformant* document must contain

- a single <teiHeader> element followed by one or more elements from the `model.resource` class; or
- in the case of a corpus or collection, a single overall <teiHeader> element followed by a series of <TEI> elements each with its own <teiHeader>

All <teiHeader> elements in a *TEI-conformant* document must include elements for:

Title Statement This should include the title of the TEI document expressed using a <titleStmt> element.

Publication Statement This should include the place and date of publication or distribution of the TEI document, expressed using the <publicationStmt> element.

Source Statement For a document derived from some previously existing document, this must include a bibliographic description of that source. For a document not so derived, this must include a brief statement that the document has no pre-existing source. In either case, this will be expressed using the <sourceDesc> element.

24.4.4 Use of the *TEI Namespace*

The Namespaces Recommendation of the W3C (?) provides a way for an XML document to combine markup from different vocabularies without risking name collision and consequent processing difficulties. While the scope of the TEI is large, there are many areas in which it makes no particular recommendation, or where it recommends that other defined markup schemas should be adopted, such as graphics or mathematics. It is also considered desirable that users of other markup schemas should be able to integrate documents using TEI markup with their own system. To meet these objectives without compromising the reliability of its encoding, a TEI-conformant document is required to make appropriate use of the TEI namespace.

Essentially all elements in a TEI Schema which represents concepts from the TEI Abstract Model belong to the TEI namespace, `http://www.tei-c.org/ns/1.0`, maintained by the TEI. A TEI-conformant document is required to declare the namespace for all the elements it contains whether these come from the TEI namespace or from other schemas.

A TEI Schema may be created which assigns TEI elements to some other namespace, or to no namespace at all. A document using such a schema cannot be considered TEI-conformant. A document which places non-TEI elements or attributes within the TEI namespace cannot be considered TEI-conformant; such practices are strongly deprecated as they may lead to serious difficulties for processing or interchange.

24.4.5 Documentation Constraint

As noted in *24.4.2. Validation Constraint* above, a TEI Schema can only be generated from a TEI ODD, which also serves to document the semantics of the elements defined by it. A TEI-conformant document should therefore always be accompanied by (or refer to) a valid *TEI ODD file* specifying which modules, elements, classes, etc. are in use together with any modifications applied, and from which a TEI Schema can be generated to validate the document. The TEI supplies a number of predefined *TEI Customization exemplar ODD files* and the schemas already generated from them (see *24.3.4. Examples of Modification*), but most projects will typically need to customize the TEI beyond what these examples provide. It is assumed, for example, that most projects will customize the TEI schema by removing those elements that are not needed for the texts they are encoding, and by providing further constraints on the attribute values and element content models the TEI provides. All such customizations must be specified by means of a valid *TEI ODD* file.

As different sorts of customization have different implications for the interchange and interoperability of TEI documents, it cannot be assumed that every customization will necessarily result in a schema that validates only TEI-conformant documents. The ODD language permits modifications which conflict with the TEI Abstract Model, even though observing this model is a requirement for TEI Conformance. The ODD language can in fact be used to describe many kinds of markup schema, including schemas which have nothing to do with the TEI at all.

Equally, it is possible to construct a TEI Schema which is identical to that derived from a given TEI ODD file without using the ODD schema. A schema can constructed simply by combining the predefined schema language fragments corresponding with the required set of TEI modules and other statements in the relevant schema language. However, the status of such a schema with respect to the `tei_all` schema cannot in general be easily determined; it may therefore be impractical to determine whether such a schema represents a clean modification or an extension. This is one reason for making the presence of a TEI ODD file a requirement for conformance.

24.4.6 Varieties of TEI Conformance

The conformance status of a given document may be assessed by answering the following questions, in the order indicated:

1. Is it a valid XML document, for which a TEI Schema exists? If not, then the document cannot be considered TEI-conformant in any sense.
2. Is the document accompanied by a TEI-conformant ODD specification describing its markup schema and intended semantics? If not, then the document can only be considered TEI-conformant if it validates against a predefined TEI Schema and conforms to the TEI abstract model.
3. Does the markup in the document correctly represent the TEI abstract model? Though difficult to assess, this is essential to TEI conformance.
4. Does the document claim that all of its elements come from some namespace other than the TEI (or no namespace)? If so, the document cannot be TEI-conformant.

5. If the document claims to use the TEI namespace, in part or wholly, do the elements associated with that namespace in fact belong to it? If not, the document cannot be TEI-conformant; if so, and if all non-TEI elements and attributes are correctly associated with other namespaces, then the document may be TEI-conformant.
6. Is the document valid according to a schema made by combining all TEI modules as well as valid according to the schema derived from its associated ODD specification? If so, the document is TEI-conformant.
7. Is the document valid according to the schema derived from its associated ODD specification, but not according to `tei_all`? If so, the document uses a TEI extension.
8. Is it possible automatically to transform the document into a document which is valid according to `tei_all`, using only information supplied in the accompanying ODD and without loss of information? If so, the document is TEI-conformant.

In the following table, we examine more closely some specific, though imaginary, cases:

	A	B	C	D	E	F	G	H
Conforms to TEI Abstract Model	Y	N	Y	Y	?	Y	N	?
Valid ODD present	Y	Y	Y	Y	Y	Y	Y	N
Uses only non-TEI namespace(s) or none	N	N	N	N	Y	N	Y	N
Uses TEI and other namespaces correctly	Y	Y	N	Y	N	Y	N	Y
Document is valid as a subset of `tei_all`	Y	N	Y	N	N	Y	N	Y
Document can be converted automatically to a form which is valid as a subset of `tei_all`	Y	N	Y	N	N	Y	N	?

We assume firstly that each sample document assessed here is a well-formed XML document, and that it is valid against some schema.

The document in column A is TEI-conformant. Its tagging follows the TEI Abstract Model, both as regards syntactic constraints (its <l> elements appear within elements and not the reverse) and semantic constraints (its <l> elements appear to contain verse lines rather than typographic ones). It is accompanied by a valid ODD which documents exactly how it uses the TEI. All the TEI-defined elements and attributes in the document are placed in the TEI namespace. The schema against which it is valid is a 'clean' subset of the `tei_all` schema.

The document in column B is not a TEI document. Although it is accompanied by a valid TEI ODD, the resulting schema includes some 'unclean' modifications, and represents some concepts from the TEI Abstract Model using non-TEI elements; for example, it re-defines the content model of <p> to permit within it, and it includes an element `<pageTrimming>` which appears to have the same meaning as the existing TEI <fw> element, but the equivalence is not made explicit in the ODD. It uses the TEI namespace correctly to identify the TEI elements it contains, but the ODD does not contain enough information automatically to convert its non-TEI elements into TEI equivalents.

The document in column C is TEI conformant. It is almost the same as the document in column A, except that the names of the elements used are not those specified for the TEI namespace. Because the ODD accompanying it contains an exact mapping for each element name (using the <altIdent> element) and there are no name conflicts, it is possible to make an automatic conversion of this document.

The document in column D is a TEI Extension. It combines elements from its own namespace with unmodified TEI elements in the TEI namespace. Its usage of TEI elements conforms to the TEI Abstract Model. Its ODD defines a new `<blort>` element which has no exact TEI equivalent, but which is assigned to an existing TEI class; consequently its schema is not a clean subset of `tei_all`. If the associated ODD provided a way of mapping this element to an existing TEI element, then this would be TEI-conformant.

The document in column E is superficially similar to document D, but because it does not use any namespace declarations (or, equivalently, it assigns unmodified TEI elements to its own namespace), it may contain name collisions; there is no way of knowing whether a <p> within it is the same as the TEI's <p> or has some other meaning. The accompanying ODD file may be used to provide the human reader with information about equivalently named elements in the TEI namespace, and hence to determine whether the document is valid with respect to the TEI Abstract Model but this is not an automatable process. In particular, cases of apparent conflict (for example use of an element <p> to represent a concept not in the TEI Abstract Model but in the abstract model of some other system,

whose namespace has been removed as well) cannot be reliably resolved. By our current definition therefore, this is not a TEI document.

The document in column F is TEI-conformant. The difference between it and that in column D is that the new element `<blort>` which is used in this document is a specialization of an existing TEI element, and the ODD in which it is defined specifies the mapping (a `<my:blort>` may be automatically converted to a <tei:seg type="blort">, for example). For this to work, however, the `<blort>` must observe the same syntactic constraints as the <seg>; if it does not, this would also be a case of TEI Extension.

The document in column G is not a TEI document. Its structure is fully documented by a valid TEI ODD, but it does not claim to represent the TEI Abstract Model, does not use the TEI namespace, and is not intended to validate against any TEI schema.

The document in column H is very like that in column A, but it lacks an accompanying ODD. Instead, the schema used to validate it is produced simply by combining TEI schema fragments in the same way as an ODD processor would, given the ODD. If the resulting schema is a clean subset of `tei_all`, such a document is indistinguishable from a TEI-conformant one, but there is no way of determining (without inspection) whether this is the case if any modification or extension has been applied. Its status is therefore, like that of Text E, impossible to determine.

24.5 Implementation of an ODD System

This section specifies how a processing system may take advantage of the markup specification elements documented in chapter *23. Documentation Elements* of these Guidelines in order to produce project specific user documentation, schemas in one or more schema languages, and validation tools for other processors.

The specifications in this section are illustrative but not normative. Its function is to further illustrate the intended scope and application of the elements documented in chapter *23. Documentation Elements*, since it is believed that these may have application beyond the areas directly addressed by the TEI.

An ODD processing system has to accomplish two main tasks. A set of selections, deletions, changes, and additions supplied by an ODD customization (as described in *24.3. Customization*) must first be merged with the published TEI P5 ODD specifications. Next, the resulting unified ODD must be processed to produce the desired outputs.

An ODD processor is not required to do these two stages in sequence, but that may well be the simplest approach; the ODD processing tools currently provided by the TEI Consortium, which are also used to process the source of these Guidelines, adopt this approach.

24.5.1 Making a Unified ODD

An ODD customization must contain a single <schemaSpec> element, which defines the schema to be constructed.

`<schemaSpec>` (schema specification) generates a TEI-conformant schema and documentation for it.

- `@start` specifies entry points to the schema, i.e. which patterns may be used as the root of documents conforming to it.
- `@prefix` specifies a default prefix which will be prepended to all patterns relating to TEI elements, unless otherwise stated.
- `@targetLang` (target language) specifies which language to use when creating the objects in a schema if names for elements or attributes are available in more than one language.
- `@docLang` (documentation language) specifies which languages to use when creating documentation if the description for an element, attribute, class or macro is available in more than one language.

Amongst other attributes inherited from the `att.identified` class, this element also carries a required *ident* attribute. This provides a name for the generated schema, which other components of the processing system may use to refer to the schema being generated, e.g. in issuing error messages or as part of the generated output schema file or files. The *ns* attribute may be used to specify the default namespace within which elements valid against the resulting schema belong, as discussed in *24.3.2. Modification and Namespaces*.

The <schemaSpec> element contains an unordered series of specialized elements, each of which is of one of the following four types:

specifications elements from the class `model.oddDecl` (by default <elementSpec>, <classSpec>, <moduleSpec>,

and <macroSpec>); these must have a *mode* attribute which determines how they will be processed.[140] If the value of *mode* is add, then the object is simply copied to the output, but if it is change, delete, or replace, then it will be looked at by other parts of the process.

references to specifications <specGrpRef> elements refer to <specGrp> elements that occur elsewhere in this, or another, document. A <specGrp> element, in turn, groups together a set of ODD specifications (among other things, including further <specGrpRef> elements). The use of <specGrp> and <specGrpRef> permits the ODD markup to occur at the points in documentation where they are discussed, rather than all inside <schemaSpec>. The *target* attribute of any <specGrpRef> should be followed, and the <elementSpec>, <classSpec>, and <macroSpec>, elements in the corresponding <specGrp> should be processed as described in the previous item; <specGrpRef> elements should be processed as described here.

references to TEI Modules <moduleRef> elements with *key* attributes refer to components of the TEI. The value of the *key* attribute matches the *ident* attribute of the <moduleSpec> element defining a TEI module. The *key* must be dereferenced by some means, such as reading an XML file with the TEI ODD specification (either from the local hard drive or off the Web), or looking up the reference in an XML database (again, locally or remotely); whatever means is used, it should return a stream of XML containing the element, class, and macro specifications collected together in the specified module. These specification elements are then processed in the same way as if they had been supplied directly within the <schemaSpec> being processed.

references to external modules a <moduleRef> element may also refer to a compatible external module by means of its *url* attribute; the content of such modules, which must be available in the RELAX NG XML syntax, are passed directly and without modification to the output schema when that is created.

Each object obtained from the TEI ODD specification using <moduleRef> by means of the *key* attribute must be checked against objects in the customization <schemaSpec> according to the following rules:

1. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of delete, then the object from the module is ignored;
2. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of replace, then the object from the module is ignored, and the one from the ODD customization is used in its place;
3. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of change, then the two objects must be merged, as described below;
4. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of add, then an error condition should be raised;
5. otherwise, the object from the module is copied to the result.

To merge two objects with the same *ident*, their component attributes and child elements must be looked at recursively. Each component may fall into one of the following four categories:

1. Some components may occur only once within the merged object (for example attributes, and <altIdent>, <content>, or <classes> elements). If such a component is found in the ODD customization, it will be copied to the output; if it is not found there, but is present in the TEI ODD specification, then that will be copied to the output.
2. Some components are grouping objects (<attList>, <valList>, for example); these are always copied to the output, and their children are then processed following the rules given in this list.
3. Some components are 'identifiable': this means that they are members of the `att.identified` class from which they inherit the *ident* attribute; examples include <attDef> and <valItem>. A component of this type will be processed according to its *mode* attribute, following the rules given above.
4. Some components may occur multiple times, but are neither grouped nor identifiable. Examples include the <desc>, <exemplum>, <remarks>, <listRef>, <datatype> and <defaultVal> elements, and the members of `model.identSynonyms`, i.e., the <equiv>, <altIdent>, and <gloss>, elements. These should be copied from both the TEI ODD specification and the ODD customization, and all occurrences included in the output.

[140] An ODD processor should recognize as erroneous such obvious inconsistencies as an attempt to include an <elementSpec> in add mode for an element which is already present in an imported module.

A special problem arises with elements which are members of attribute classes, as they are permitted to override attributes inherited from a class. For example, consider this simple modification:

```
<elementSpec ident="p">
  <classes>
    <memberOf key="att.typed"/>
  </classes>
<!-- ... -->
</elementSpec>
```

The effect of its membership in the `att.typed` class is to provide <p> with a *type* attribute and a *subtype* attribute. If we wish <p> to *not* have *subtype*, we could extend the customization in our schema as follows:

```
<elementSpec ident="p">
  <classes>
    <memberOf key="att.typed"/>
  </classes>
<!-- ... -->
  <attList>
    <attDef ident="subtype" mode="delete"/>
  </attList>
</elementSpec>
```

This means that when <memberOf key="att.typed"/> is processed, that class is looked up, each attribute which it defines is examined in turn, and the customization is searched for an override. If the modification is of the attribute class itself, work proceeds as usual; if, however, the modification is at the element level, the class reference is deleted and a series of <attRef> elements is added to the element, one for each attribute inherited from the class. Since attribute classes can themselves be members of other attribute classes, membership must be followed recursively.

The effect of the concatenation of unidentifiable components should be considered carefully. An original may have

```
<elementSpec ident="p">
  <desc>marks paragraphs in prose.</desc>
<!-- ... -->
</elementSpec>
```

which would usefully be extended with this:

```
<elementSpec ident="p" mode="change">
  <desc xml:lang="es">marca párrafos en prosa.</desc>
<!-- ... -->
</elementSpec>
```

to provide an alternate description in another language. Nothing prevents the user from supplying <desc> several times in the same language, and subsequent applications will have to decide what that may mean.

Similar considerations apply to multiple example elements, though these are less likely to cause problems in documentation. Note that existing examples can only be deleted by supplying a completely new <elementSpec> in replace mode, since the <exemplum> element is not identifiable.

In the processing of the content models of elements and the content of macros, deleted elements may require special attention.[141] A content model like this:

[141] The carthago program behind the Pizza Chef application, written by Michael Sperberg-McQueen for TEI P3 and P4, went to very great efforts to get this right. The XSLT transformations used by the P5 Roma application are not as sophisticated, partly because the RELAX NG language is more forgiving than DTDs.

```
<elementSpec ident="person">
<!-- ... -->
  <content>
    <alternate>
      <classRef key="model.pLike"
        minOccurs="1" maxOccurs="unbounded"/>
      <alternate minOccurs="0"
        maxOccurs="unbounded">
        <classRef key="model.personPart"/>
        <classRef key="model.global"/>
      </alternate>
    </alternate>
  </content>
<!-- ... -->
</elementSpec>
```

requires no special treatment because everything is expressed in terms of model classes; if the class `model.personPart` is deleted explicitly, or removed because all of its members have been deleted, then `model.global` is left as the only child of the inner <alternate>. An ODD processor may or may not elect to simplify the resulting choice between nothing and `model.global` by removing the wrapper <alternate> element. However, such simplification may be considerably more complex in the general case and an ODD processor is therefore likely to be more successful in carrying out such simplification as a distinct stage during processing of ODD sources.

If an element refers directly to an element child, like this:

```
<elementSpec ident="figure">
<!-- ... -->
  <content>
    <alternate minOccurs="0"
      maxOccurs="unbounded">
      <classRef key="model.pLike"/>
      <classRef key="model.global"/>
      <elementRef key="figure"/>
      <elementRef key="figDesc"/>
      <classRef key="model.graphicLike"/>
      <classRef key="model.headLike"/>
    </alternate>
  </content>
<!-- ... -->
</elementSpec>
```

and <figDesc> has been deleted,[142] it will be necessary to remove that reference, or the resulting schema will be invalid.

The result of the work carried out should be a new <schemaSpec> which contains a complete and internally consistent set of element, class, and macro specifications, possibly also including <moduleRef> elements with *url* attributes identifying external modules.

24.5.2 Generating Schemas

Assuming that any modifications have been resolved, as outlined in the previous section, making a schema is now a four stage process:

1. all datatype and other macro specifications must be collected together and declared at the start of the output schema;

[142]Note that deletion of required elements will cause the schema specification to accept as valid documents which cannot be TEI-conformant, since they no longer conform to the TEI Abstract Model; conformance topics are addressed in more detail in *24.4. Conformance*.

2. all classes must be declared in the right order (order is significant because since some classes reference others);
3. all elements are declared;
4. any <moduleRef> elements with a *url* attribute identifying an external schema must be processed.

Working in this order gives the best chance of successfully supporting all the schema languages. However, there are a number of obstacles to overcome along the way.

An ODD processor may choose to use any desired schema language or languages for its schema output, since ODD specifications are expressed as far as possible in a form independent of any schema language. The current TEI ODD processing system produces schema output in the three main schema languages as follows:

- A RELAX NG (XML) schema is generated by converting content models, datatypes, and macro specifications provided within the ODD specification; a version re-expressed in the RELAX NG compact syntax is generated using James Clark's trang application.
- A DTD schema is generated by converting the RELAX NG content models to DTD language, often simplifying it to allow for the less-sophisticated output language.
- A W3C Schema schema is created by generating a RELAX NG schema and then using James Clark's trang application.

Note that the method used to generate W3C Schema means that a processor must ensure that the RELAX NG it generates follows the subset which trang is able to translate properly (see further below)—this may involve simple trial and error.

Other projects may decide to follow a different route, perhaps implementing a direct ODD to W3C Schema translator.

Secondly, it is possible to create two rather different styles of schema. On the one hand, the schema can try to maintain all the flexibility of ODD by using the facilities of the schema language for parameterization; on the other, it can remove all customization features and produce a flat result which is not suitable for further manipulation. The TEI project currently generates both styles of schema; the first as a set of schema fragments in DTD and RELAX NG languages, which can be included as modules in other schemas, and customized further; the second as the output from a processor such as Roma, in which many of the parameterization features have been removed.

The difference between the schema styles may be illustrated by considering this ODD specification:

```
<elementSpec module="drama"
  ident="performance">
<!-- ... -->
  <classes>
    <memberOf key="model.frontPart.drama"/>
  </classes>
  <content>
    <sequence>
      <alternate minOccurs="0"
        maxOccurs="unbounded">
        <classRef key="model.divTop"/>
        <classRef key="model.global"/>
      </alternate>
      <sequence minOccurs="1"
        maxOccurs="unbounded">
        <classRef key="model.common"/>
        <classRef key="model.global"
          minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
      <sequence minOccurs="0"
        maxOccurs="unbounded">
        <classRef key="model.divBottom"/>
        <classRef key="model.global"
          minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
```

```
    </sequence>
  </content>
<!-- ... -->
</elementSpec>
```

A simple rendering to RELAX NG produces this:

```
  performance =
element performance {
(model.divTop | model.global)*,
(model.common, model.global*)+,
(model.divBottom, model.global*)*
att.global.attribute.xmlspace,
att.global.attribute.xmlid,
att.global.attribute.n,
att.global.attribute.xmllang,
att.global.attribute.rend,
att.global.attribute.xmlbase,
att.global.linking.attribute.corresp,
att.global.linking.attribute.synch,
att.global.linking.attribute.sameAs,
att.global.linking.attribute.copyOf,
att.global.linking.attribute.next,
att.global.linking.attribute.prev,
att.global.linking.attribute.exclude,
att.global.linking.attribute.select
}
```

In the above, a subsequent redefinition of the attribute class (such as `att.global`) would have no effect, since references to such classes have been expanded to reference their constituent attributes.

The equivalent parameterized version might look like this:

```
  performance =
element performance { performance.content, performance.attributes }
performance.content =
(model.divTop | model.global)*,
(model.common, model.global*)+,
(model.divBottom, model.global*)*
performance.attributes = att.global.attributes, empty
```

Here, the attribute class `att.global` is provided via an explicit reference (`att.global.attributes`), and can therefore be redefined. Moreover, the attributes are separated from the content model, allowing either to be overridden.

In the remainder of these section, the terms *simple schema* and *parameterized schema* are used to distinguish the two schema types. An ODD processor is not required to support both, though the simple schema output is generally preferable for most applications.

Thirdly, the problem of missing components must be resolved. For example, consider this (fictitious) model for <sp>:

```
<elementSpec ident="sp">
<!-- ... -->
  <content>
    <sequence minOccurs="1" maxOccurs="1">
      <classRef key="model.global"
        minOccurs="0" maxOccurs="unbounded"/>
      <sequence minOccurs="0" maxOccurs="1">
        <elementRef key="speaker"/>
        <classRef key="model.global"
          minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </sequence>
  </content>
<!-- ... -->
</elementSpec>
```

This proposes anything from the class `model.global`, followed optionally by a <speaker> element followed by anything from the `model.global` class. What happens if <speaker> is removed from the schema? The following would result:

```
<elementSpec ident="sp">
<!-- ... -->
  <content>
    <sequence minOccurs="1" maxOccurs="1">
      <classRef key="model.global"
        minOccurs="0" maxOccurs="unbounded"/>
      <classRef key="model.global"
        minOccurs="0" maxOccurs="unbounded"/>
    </sequence>
  </content>
<!-- ... -->
</elementSpec>
```

which is illegal in DTD and W3C schema languages, since for a given member of `model.global` it is impossible to be sure which rule is being used. This situation is not detected when RELAX NG is used, since the language is able to cope with non-deterministic content models of this kind and does not require that only a single rule be used.

Finally, an application will need to have some method of associating the schema with document instances that use it. The TEI does not mandate any particular method of doing this, since different schema languages and processors vary considerably in their requirements. ODD processors may wish to build in support for some of the methods for associating a document instance with a schema. The TEI does not mandate any particular method, but does suggest that those which are already part of XML (the DOCTYPE declaration for DTDs) and W3C Schema (the *xsi:schemaLocation* attribute) be supported where possible.

In order for the *xsi:schemaLocation* attribute to be valid when a document is validated against either a DTD or a RELAX NG schema, ODD processors may wish to add declarations for this attribute and its namespace to the root element, even though these are not part of the TEI *per se*. For DTDs this means adding

```
  xsi:schemaLocation CDATA #IMPLIED xmlns:xsi CDATA #FIXED 'http://www.w3.org/2001/XMLSchema-inst
```

to the list of attributes on the root element, which permits the non-namespace-aware DTD language to recognize the `xsi:schemaLocation` notation. For RELAX NG, the namespace and attribute would be declared in the usual way:

```
namespace xsi = "http://www.w3.org/2001/XMLSchema-instance"
```

and

```
attribute xsi:schemaLocation { list { teidata.namespace, teidata.pointer }+ }
```

inside the root element declaration.

Note that declaration of the *xsi:schemaLocation* attribute in a W3C Schema schema is not permitted. Therefore, if W3C Schemas are being generated by converting the RELAX NG schema (for example, with trang), it may be necessary to perform that conversion prior to adding the *xsi:schemaLocation* declaration to the RELAX NG.

It is recognized that this is an unsatisfactory solution, but it permits users to take advantage of the W3C Schema facility for indicating a schema, while still permitting documents to be validated using DTD and RELAX NG processors without any conflict.

24.5.3 Names and Documentation in Generated Schemas

When processing class, element, or macro specifications, there are three general rules:

1. If a RELAX NG pattern or DTD parameter entity is being created, its name is the value of the corresponding *ident* attribute, prefixed by the value of any *prefix* attribute on <schemaSpec>. This allows for elements from an external schema to be mixed in without risk of name clashes, since all TEI elements can be given a distinctive prefix such as tei_. Thus

```
<schemaSpec ident="test" prefix="tei_">
  <elementSpec ident="sp">
<!--...-->
  </elementSpec>
</schemaSpec>
```

   may generate a RELAX NG (compact syntax) pattern like this:

```
tei_ sp = element sp { ... }
```

   References to these patterns (or, in DTDs, parameter entities) also need to be prefixed with the same value.

2. If an element or attribute is being created, its default name is the value of the *ident* attribute, but if there is an <altIdent> child, its content is used instead.
3. Where appropriate, the documentation strings in <gloss> and <desc> should be copied into the generated schema. If there is only one occurrence of either of these elements, it should be used regardless, but if there are several, local processing rules will need to be applied. For example, if there are several with different values of *xml:lang*, a locale indication in the processing environment might be used to decide which to use. For example,

```
<elementSpec module="core" ident="head">
  <equiv/>
  <gloss>heading</gloss>
  <gloss xml:lang="fr">en-tête</gloss>
  <gloss xml:lang="es">encabezamiento</gloss>
  <gloss xml:lang="it">titolo</gloss>
<!-- ... -->
</elementSpec>
```

might generate a RELAX NG schema fragment like the following, if the locale is determined to be French:

```
    head =
  ## en-tête
  element head { head.content, head.attributes }
```

Alternatively, a selection might be made on the basis of the value of the *version* attribute which these elements carry as members of the `att.translatable` class.

In addition, there are three conventions about naming patterns relating to classes; ODD processors need not follow them, but those reading the schemas generated by the TEI project will find it necessary to understand them:

1. when a pattern for an attribute class is created, it is named after the attribute class identifier (as above) suffixed by `.attributes` (e.g. `att.editLike.attributes`);
2. when a pattern for an attribute is created, it is named after the attribute class identifier (as above) suffixed by `.attribute.` and then the identifier of the attribute (e.g. `att.editLike.attribute.resp`);
3. when a parameterized schema is created, each element generates patterns for its attributes and its contents separately, suffixing respectively `.attributes` and `.contents` to the element name.

24.5.4 Making a RELAX NG Schema

To create a RELAX NG schema, the processor processes every <macroSpec>, <classSpec>, and <elementSpec> in turn, creating a RELAX NG pattern for each, using the naming conventions listed above. The order of declaration is not important, and a processor may well sort them into alphabetical order of identifier.

A complete RELAX NG schema must have an `<rng:start>` element defining which elements can occur as the root of a document. The ODD <schemaSpec> has an optional *start* attribute, containing one or more patterns, which can be used to construct the `<rng:start>`. A pattern normally corresponds to an element name, but if a prefix (see above, *24.5.3. Names and Documentation in Generated Schemas*) is supplied for an element, the pattern consists of the prefix name with the element name.

24.5.4.1 Macros

An ODD macro generates a corresponding RELAX NG pattern by processing the body of the <content> element in the same way as elsewhere. Thus

```
<macroSpec module="tei"
  ident="macro.phraseSeq">
  <content>
    <alternate minOccurs="0"
      maxOccurs="unbounded">
      <textNode/>
      <classRef key="model.gLike"/>
      <classRef key="model.phrase"/>
      <classRef key="model.global"/>
    </alternate>
  </content>
</macroSpec>
```

produces the following

```
<rng:define name="macro.phraseSeq">
  <rng:zeroOrMore>
    <rng:choice>
      <rng:text/>
```

```
      <rng:ref  name="model.gLike"/>
      <rng:ref  name="model.phrase"/>
      <rng:ref  name="model.global"/>
    </rng:choice>
  </rng:zeroOrMore>
</rng:define>
```

24.5.4.2 Classes

An ODD model class always generates a RELAX NG pattern definition listing all the members of the class in alternation. For example

```
<classSpec  module="tei"  type="model"
  ident="model.measureLike">
<!-- ... -->
</classSpec>
```

will produce something like the following:

```
<rng:define  name="model.measureLike">
  <rng:choice>
    <rng:ref  name="num"/>
    <rng:ref  name="measure"/>
    <rng:ref  name="measureGrp"/>
  </rng:choice>
</rng:define>
```

assuming that the elements <num>, <measure>, and <measureGrp> are all defined in the schema concerned as members of that class. A model declaration may also generate a number of other patterns corresponding with sequences or alternations of the class members:

```
<rng:define  name="model.measureLike_sequence">
  <rng:ref  name="num"/>
  <rng:ref  name="measure"/>
  <rng:ref  name="measureGrp"/>
</rng:define>
<rng:define  name="model.measureLike_sequenceOptional">
  <rng:optional>
    <rng:ref  name="num"/>
  </rng:optional>
  <rng:optional>
    <rng:ref  name="measure"/>
  </rng:optional>
  <rng:optional>
    <rng:ref  name="measureGrp"/>
  </rng:optional>
</rng:define>
<rng:define  name="model.measureLike_sequenceOptionalRepeatable">
  <rng:zeroOrMore>
    <rng:ref  name="num"/>
  </rng:zeroOrMore>
  <rng:zeroOrMore>
    <rng:ref  name="measure"/>
```

```
  </rng:zeroOrMore>
  <rng:zeroOrMore>
    <rng:ref  name="measureGrp"/>
  </rng:zeroOrMore>
</rng:define>
<rng:define  name="model.measureLike_sequenceRepeatable">
  <rng:oneOrMore>
    <rng:ref  name="num"/>
  </rng:oneOrMore>
  <rng:oneOrMore>
    <rng:ref  name="measure"/>
  </rng:oneOrMore>
  <rng:oneOrMore>
    <rng:ref  name="measureGrp"/>
  </rng:oneOrMore>
</rng:define>
```

where the pattern name is created by appending an underscore and the name of the generation type to the class name.

When classes are referenced using the <classRef> element, it is possible to indicate which of the available patterns is required by means of the *expand* attribute.

Attribute classes work by producing a pattern containing definitions of the appropriate attributes. So

```
<classSpec  module="verse"  type="atts"
  ident="att.enjamb">
  <attList>
    <attDef  ident="enjamb"  usage="opt">
      <equiv/>
      <desc>indicates whether the end of a verse line is marked by enjambement.</desc>
      <datatype>
        <dataRef  key="teidata.enumerated"/>
      </datatype>
      <valList  type="open">
        <valItem  ident="no">
          <equiv/>
          <desc>the line is end-stopped </desc>
        </valItem>
        <valItem  ident="yes">
          <equiv/>
          <desc>the line in question runs on into the next </desc>
        </valItem>
        <valItem  ident="weak">
          <equiv/>
          <desc>the line is weakly enjambed </desc>
        </valItem>
        <valItem  ident="strong">
          <equiv/>
          <desc>the line is strongly enjambed</desc>
        </valItem>
      </valList>
    </attDef>
  </attList>
</classSpec>
```

produces

```
<rng:define  name="att.enjamb.attributes">
  <rng:ref  name="att.enjamb.attribute.enjamb"/>
  <rng:empty/>
</rng:define>
<rng:define  name="att.enjamb.attribute.enjamb">
  <rng:optional>
    <rng:attribute  name="enjamb">
      <a:documentation>(enjambement) indicates whether the end of a verse line is
marked by
           enjambement. Sample values include: 1] no; 2] yes; 3] weak; 4]
           strong</a:documentation>
      <rng:ref  name="teidata.enumerated"/>
    </rng:attribute>
  </rng:optional>
</rng:define>
```

Since the processor may have expanded the attribute classes already, separate patterns are generated for each attribute in the class as well as one for the class itself. This allows an element to refer directly to a member of a class. Notice that the <desc> element is used to add an `<a:documentation>` element to the schema, which some editors use to provide help during composition. The <desc> elements in the <valList> are used to create the human-readable sentence 'Sample values include: 1] no; 2] yes; 3] weak; 4] strong' Naturally, this behaviour is not mandatory; and other ODD processors may create documentation in other ways, or ignore those parts of the ODD specifications when creating schemas.

An individual attribute consists of an `<rng:attribute>` with a *name* attribute derived according to the naming rules described above (*24.5.3. Names and Documentation in Generated Schemas*). In addition, the ODD model supports a <defaultVal>, which is transformed to a *defaultValue* attribute in the namespace `http://relaxng.org/ns/compatibility/annotations/1.0` on the `<rng:attribute>`. The body of the attribute is taken from the <datatype> child, unless there is a supporting <valList> with a *type* value of closed. In that case an `<rng:choice>` is created, listing the allowed values. Thus the following attribute definition

```
<attDef  ident="full"  usage="opt">
  <defaultVal>yes</defaultVal>
  <valList  type="closed">
    <valItem  ident="yes">
      <desc>the name component is spelled out in full.</desc>
    </valItem>
    <valItem  ident="abb">
      <gloss>abbreviated</gloss>
      <desc>the name component is given in an abbreviated form.</desc>
    </valItem>
    <valItem  ident="init">
      <gloss>initial letter</gloss>
      <desc>the name component is indicated only by one initial.</desc>
    </valItem>
  </valList>
</attDef>
```

may generate this RELAX NG code:

```
<rng:define  name="att.full">
  <rng:optional>
    <rng:attribute  name="full"
      a:defaultValue="yes">
```

```
     <rng:choice>
       <rng:value>yes</rng:value>
       <a:documentation> the name component is spelled out in full. </a:documentation>
       <rng:value>abb</rng:value>
       <a:documentation> the name component is given in an abbreviated form.
</a:documentation>
       <rng:value>init</rng:value>
       <a:documentation> the name component is indicated only by one initial.
       </a:documentation>
     </rng:choice>
   </rng:attribute>
  </rng:optional>
</rng:define>
```

Note the use of the `http://relaxng.org/ns/compatibility/annotations/1.0` namespace to provide default values and documentation.

24.5.4.3 Elements

An <elementSpec> produces a RELAX NG specification in two parts; firstly, it must generate an `<rng:define>` pattern by which other elements can refer to it, and then it must generate an `<rng:element>` with the content model and attributes. It may be convenient to make two separate patterns, one for the element's attributes and one for its content model.

The content model is created by processing the TEI declarations found within the <content> element; ; the attributes are processed in the same way as those from attribute classes, described above.

24.5.5 Making a DTD

Generation of DTDs largely follows the same pattern as RELAX NG generation, with one important exception—*the order of declaration matters.* A DTD may not refer to an entity which has not yet been declared. Since both macros and classes generate DTD parameter entities, the TEI Guidelines are constructed so that they can be declared in the right order. A processor must therefore work in the following order:

1. declare all model classes which have a *predeclare* value of true
2. declare all macros which have a *predeclare* value of true
3. declare all other classes
4. declare the modules (if DTD fragments are being constructed)
5. declare any remaining macros
6. declare the elements and their attributes

Let us consider a complete example, a simple element with no attributes of its own:

```
<elementSpec  module="namesdates"
  ident="faith">
  <desc>specifies the faith, religion, or belief set of a person.</desc>
  <classes>
    <memberOf  key="model.persStateLike"/>
    <memberOf  key="att.editLike"/>
    <memberOf  key="att.datable"/>
  </classes>
  <content>
    <macroRef  key="macro.phraseSeq"/>
  </content>
</elementSpec>
```

If DTD fragments are being generated (for use as described in *24.5.7. Using TEI Parameterized Schema Fragments*), this will result in the following:

```
  <!ENTITY % faith 'INCLUDE' >
<![ %faith; [

<!--doc:specifies the faith,  religion, or belief set of a person. -->
<!ELEMENT %n.faith; %om.RR; %macro.phraseSeq;>
<!ATTLIST %n.faith; xmlns CDATA "http://www.tei-c.org/ns/1.0">
<!ATTLIST %n.faith;
%att.global.attributes;
%att.editLike.attributes;
%att.datable.attributes; >
]]>
```

Here the whole stanza is contained in a marked section (for use as described in *24.5.7.2. Inclusion and Exclusion of Elements*), the element name is parameterized (see *24.5.7.3. Changing the Names of Generic Identifiers*), and the class attributes are entity references derived from the <memberOf> records in <classes>. Note the additional attribute which provides a default *xmlns* declaration for the element; the effect of this is that if the document is processed by a DTD-aware XML processor, the namespace declaration will be present automatically without the document author even being aware of it.

A simpler rendition for a flattened DTD generated from a customization will result in the following, with no containing marked section, and no parameterized name:

```
  <!ELEMENT faith %macro.phraseSeq;>
<!ATTLIST faith xmlns CDATA "http://www.tei-c.org/ns/1.0">
<!ATTLIST faith
%att.global.attribute.xmlspace;
%att.global.attribute.xmlid;
%att.global.attribute.n;
%att.global.attribute.xmllang;
%att.global.attribute.rend;
%att.global.attribute.xmlbase;
%att.global.linking.attribute.corresp;
%att.global.linking.attribute.synch;
%att.global.linking.attribute.sameAs;
%att.global.linking.attribute.copyOf;
%att.global.linking.attribute.next;
%att.global.linking.attribute.prev;
%att.global.linking.attribute.exclude;
%att.global.linking.attribute.select;
%att.editLike.attribute.cert;
%att.editLike.attribute.resp;
%att.editLike.attribute.evidence;
%att.datable.w3c.attribute.period;
%att.datable.w3c.attribute.when;
%att.datable.w3c.attribute.notBefore;
%att.datable.w3c.attribute.notAfter;
%att.datable.w3c.attribute.from;
%att.datable.w3c.attribute.to;>
```

Here the attributes from classes have been expanded into individual entity references.

24.5.6 Generating Documentation

In Donald Knuth's literate programming terminology (?), the previous sections have dealt with the *tangle* process; to generate documentation, we now turn to the *weave* process.

An ODD customization may consist largely of general documentation and examples, requiring no ODD-specific processing. It will normally however also contain a <schemaSpec> element and possibly some <specGrp> fragments.

The generated documentation may be of two forms. On the one hand, we may document the customization itself, that is, only those elements (etc.) which differ in their specification from that provided by the TEI reference documentation. Alternatively, we may generate reference documentation for the complete subset of the TEI which results from applying the customization. The TEI Roma tools take the latter approach, and operate on the result of the first stage processing described in *24.5.1. Making a Unified ODD*.

Generating reference documentation for <elementSpec>, <classSpec>, and <macroSpec> elements is largely dependent on the design of the preferred output. Some applications may, for example, want to turn all names of objects into hyperlinks, show lists of class members, or present lists of attributes as tables, lists, or inline prose. Another technique implemented in these Guidelines is to show lists of potential 'parents' for each element, by tracing which other elements have them as possible members of their content models.

One model of display on a web page is shown in 36, corresponding to the <faith> element shown in section *24.5.5. Making a DTD*.

<faith>

Home | Table of Contents
Element catalogue

<**faith**> specifies the faith, religion, or belief set of a person.

Module	namesdates — 13 Names, Dates, People, and Places
Attributes	[att.editLike att.datable]

Declaration	Compact to XML format
	element faith
	{
	att.global.attributes,
	att.editLike.attributes,
	att.datable.w3c.attributes,
	att.datable.iso.attributes,
	macro.phraseSeq
	}

Example	<faith>protestant</faith>

Figure 36: Example reference documentation for `<faith>`

24.5.7 Using TEI Parameterized Schema Fragments

The TEI parameterized DTD and RELAX NG fragments make use of parameter entities and patterns for several purposes. In this section we describe their interface for the user. In general we recommend use of ODD instead of this technique, which has been retained only for compatability reasons.

24.5.7.1 Selection of Modules

Special-purpose parameter entities are used to specify which modules are to be combined into a TEI DTD. They take the form TEI.xxxxx where `xxxx` is the name of the module as given in table the table on p. 2 in *1.1. TEI Modules*. For example, the parameter entity `TEI.linking` is used to define whether or not to include the module `linking`. All such parameter entities are declared by default with the value IGNORE: to select a module, therefore, the encoder declares the appropriate parameter entities with the value INCLUDE.

For XML DTD fragments, note that some modules generate two DTD fragments: for example the `analysis` module generates fragments called `analysis-decl` and `analysis`. This is because the declarations they contain are needed at different points in the creation of an XML DTD.

The parameter entity named for the module is used as the keyword controlling a conditional marked section in the DTD fragment generated by the `tei` module. The declarations for each DTD fragment constituting the module are contained within such marked sections. For example, the parameter entity `TEI.linking` appears twice in `tei.dtd`, once for the `linking-decl` schema fragment:

```
  <!ENTITY % TEI.linking 'IGNORE' >
<![%TEI.linking;[
<!ENTITY % file.linking-decl PUBLIC '-//TEI P5//ENTITIES Linking, Segmentation, and
Alignment//EN' 'linking-decl.dtd' >
%file.linking-decl;
]] >
```

and once for the `linking` schema fragment:

```
  <![%TEI.linking;[
<!ENTITY % file.linking PUBLIC '-//TEI P5//ELEMENTS Linking, Segmentation, and
Alignment//EN' 'linking.dtd' >
%file.linking;]] >
```

If TEI.linking has its default value of IGNORE, neither declaration has any effect. If however it has the value INCLUDE, then the content of each marked section is acted upon: the parameter entities `file.linking` and `file.linking-decl` are referenced, which has the effect of embedding the content of the files they represent at the appropriate point in the DTD.

The RELAX NG schema fragments can be combined in a wrapper schema using the standard mechanism of `<rng:include>` in that language.

24.5.7.2 Inclusion and Exclusion of Elements

The TEI DTD fragments also use marked sections and parameter entity references to allow users to exclude the definitions of individual elements, in order either to make the elements illegal in a document or to allow the element to be redefined. The parameter entities used for this purpose have exactly the same name as the generic identifier of the element concerned. The default definition for these parameter entities is INCLUDE but they may be changed to IGNORE in order to exclude the standard element and attribute definition list declarations from the DTD.

The declarations for the element <p>, for example, are preceded by a definition for a parameter entity with the name `p` and contained within a marked section whose keyword is given as `%p;`:

```
  <!ENTITY % p 'INCLUDE' >
<![ %p; [
<!-- element and attribute list declaration for p here -->
]]
```

These parameter entities are defined immediately preceding the element whose declarations they control; because their names are completely regular, they are not documented further.

To define a DTD in which the element <p> is excluded therefore, the entity `p` needs to be redefined as IGNORE by ensuring that a declaration such as

```
  <!ENTITY % p 'IGNORE' >
```

is added earlier in the DTD than the default (see further *24.5.7.4. Embedding Local Modifications (DTD only)*).

Similarly, in the parameterized RELAX NG schemas, every element is defined by a pattern named after the element. To undefine an element therefore all that is necessary is to add a declaration like the following:

```
p = notAllowed
```

24.5.7.3 Changing the Names of Generic Identifiers

In the TEI DTD fragments, elements are not referred to directly by their generic identifiers; instead, the DTD fragments refer to parameter entities which expand to the standard generic identifiers. This allows users to rename elements by redefining the appropriate parameter entity. Parameter entities used for this purpose are formed by taking the standard generic identifier of the element and attaching the string n. as a prefix. Thus the standard generic identifiers for paragraphs, notes, and quotations, <p>, <note>, and <persName> are defined by declarations of the following form:

```
<!ENTITY % n.p "p">
<!ENTITY % n.note "note">
<!ENTITY % n.persName "persName">
```

Note that since all names are case-sensitive, the specific mix of uppercase and lowercase letters in the standard generic identifier must be preserved in the entity name.

These declarations are generated by an ODD processor when TEI DTD fragments are created.

In the RELAX NG schemas, all elements are normally defined using a pattern with the same name as the element (as described in *24.5.3. Names and Documentation in Generated Schemas*): for example

```
abbr = element abbr { abbr.content, abbr.attributes }
```

The easiest way of renaming the element is thus simply to rewrite the pattern with a different element name; any references use the pattern, not the element, name.

```
abbr = element abbrev { abbr.content, abbr.attributes }
```

More complex revisions, such as redefining the content of the element (defined by the pattern `abbr.content`) or its attributes (defined by the pattern `abbr.attributes`) can be accomplished in a similar way, using the features of the RELAX NG language. The recommended method of carrying out such modifications is however to use the ODD language as further described in section *23. Documentation Elements*.

24.5.7.4 Embedding Local Modifications (DTD only)

Any local modifications to a DTD (i.e. changes to a schema other than simple inclusion or exclusion of modules) are made by declarations stored in one of two local extension files, one containing modifications to the TEI parameter entities, and the other new or changed declarations of elements and their attributes. Entity declarations must be made which associate the names of these two files with the appropriate parameter entity so that the declarations they contain can be embedded within the TEI DTD at an appropriate point.

The following entities are referred to by the main `tei.dtd` file to embed portions of the TEI DTD fragments or locally developed extensions.

`TEI.extensions.ent` identifies a local file containing extensions to the TEI parameter entities

`TEI.extensions.dtd` identifies a local file containing extensions to the TEI module

For example, if the relevant files are called `project.ent` and `project.dtd`, then declarations like the following would be appropriate:

```
  <!ENTITY % TEI.extensions.ent SYSTEM 'project.ent' >
<!ENTITY % TEI.extensions.dtd SYSTEM 'project.dtd' >
```

When an entity is declared more than once, the first declaration is binding and the others are ignored. The local modifications to parameter entities should therefore be handled before the standard parameter entities themselves are declared in `tei.dtd`. The entity `TEI.extensions.ent` is referred to before any TEI declarations are handled, to allow the user's declarations to take priority. If the user does not provide a `TEI.extensions.ent` entity, the entity will be expanded to the empty string.

For example the encoder might wish to add two phrase-level elements `<it>` and `<bd>`, perhaps as synonyms for <hi rend='italics'> and <hi rend='bold'>. As described in chapter *24.3. Customization*, this involves two distinct steps: one to define the new elements, and the other to ensure that they are placed into the TEI document structure at the right place.

Creating the new declarations is done in the same way for user-defined elements as for any other; the same parameter entities need to be defined so that they may be referenced by other elements. The content models of these new elements may also reference other parameter entities, which is why they need to be declared after other declarations.

The second step involves modifying the element class to which the new elements should be attached. This requires that the parameter entity `macro.phraseSeq` should be modified to include the generic identifiers for the new elements we wish to create. The declaration for each modifiable parameter entity in the DTD includes a reference to an additional parameter entity with the same name prefixed by an `x.`; these entities are declared by default as the null string. However, in the file containing local declarations they may be redeclared to include references to the new class members:

```
  <!ENTITY % x.macro.phraseSeq 'it | bd |'>
```

and this declaration will take precedence over the default when the declaration for macro.phraseSeq is evaluated.

A Model Classes

A.1 About the Model Classes Appendix

This appendix gives you a list of model classes and links to the reference pages for them. There are 127 distinctly-named model classes in revision 113e933e2 of TEI P5 Version 4.12.0 of the TEI Guidelines.

---

model.addressLike groups elements used to represent a postal or email address. [*1. The TEI Infrastructure*]

Module tei — The TEI Infrastructure

Used by location model.correspActionPart model.pPart.data

Members address affiliation email

---

model.addrPart groups elements such as names or postal codes which may appear as part of a postal address. [*3.6.2. Addresses*]

Module tei — The TEI Infrastructure

Used by address

Members model.nameLike[model.nameLike.agent[name orgName persName] model.offsetLike[geogFeat offset] model.persNamePart[addName forename genName nameLink persPronouns roleName surname] model.placeStateLike[model.placeNamePart[bloc country district geogName placeName region settlement] climate location population state terrain trait] eventName idno lang objectName rs] addrLine postBox postCode street

---

model.annotationLike groups elements used to represent annotations. [*17.10. The standOff Container*]

Module tei — The TEI Infrastructure

Used by listAnnotation model.standOffPart

Members annotation annotationBlock note

---

model.annotationPart.body groups elements which may be used as an <annotation> body.

Module tei — The TEI Infrastructure

Used by annotation

Members note ptr ref

---

model.applicationLike groups elements used to record application-specific information about a document in its header.

Module tei — The TEI Infrastructure

Used by appInfo

Members application

---

model.attributable groups elements that contain a word or phrase that can be attributed to a source. [*3.3.3. Quotation 4.3.2. Floating Texts*]

Module tei — The TEI Infrastructure

Used by cit macro.phraseSeq model.inter sp

Members model.quoteLike[cit quote] floatingText said

---

model.availabilityPart groups elements such as licences and paragraphs of text which may appear as part of an availability statement. [*2.2.4. Publication, Distribution, Licensing, etc.*]

Module tei — The TEI Infrastructure

Used by availability

Members licence

---

model.biblLike groups elements containing a bibliographic description. [*3.12. Bibliographic Citations and References*]

Module tei — The TEI Infrastructure

Used by broadcast cit climate event listBibl location model.entryPart.top model.inter model.msItemPart model.personPart model.standOffPart object org place population relatedItem scriptStmt sourceDesc state taxonomy terrain trait

Members bibl biblFull biblStruct listBibl msDesc

model.castItemPart groups component elements of an entry in a cast list, such as dramatic role or actor's name.

Module tei — The TEI Infrastructure

Used by castItem

Members actor role roleDesc

---

model.catDescPart groups component elements of the TEI header Category Description.

Module tei — The TEI Infrastructure

Used by catDesc

Members textDesc

---

model.certLike groups elements which are used to indicate uncertainty or precision of other elements.

Module tei — The TEI Infrastructure

Used by certainty gap interp join precision respons space substJoin

Members certainty precision respons

---

model.choicePart groups elements (other than <choice> itself) which can be used within a <choice> alternation. [*3.5. Simple Editorial Changes*]

Module tei — The TEI Infrastructure

Used by choice

Members abbr am corr ex expan orig reg seg sic supplied unclear

---

model.cmc includes the CMC-specific element <post> and makes it available on the divPart level. This allows for using (and combining) occurrences of <post>, <u>, <incident>, and <kinesic> in one and the same in order to be able to represent the combined use of written and spoken posts, utterances, and nonverbal acts on the GUI of multimodal CMC environments.

Module tei — The TEI Infrastructure

Used by macro.specialPara.cmc model.common

Members post

---

model.common groups common chunk- and inter-level elements. [*1.3. The TEI Class System*]

Module tei — The TEI Infrastructure

Used by argument body castList div div1 div2 div3 div4 div5 div6 div7 epigraph epilogue figure performance postscript prologue set

Members model.cmc[post] model.divPart[model.divPart.spoken[annotationBlock u] model.lLike[l] model.pLike[ab p] eTree forest graph lg listForest sp spGrp tree] model.entryLike[entry entryFree superEntry] model.inter[model.attributable[model.quoteLike[cit quote] floatingText said] model.biblLike[bibl biblFull biblStruct listBibl msDesc] model.egLike[eg egXML] model.labelLike[desc label] model.listLike[list listApp listEvent listNym listObject listOrg listPerson listPlace listRelation listWit table] model.oddDecl[classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec outputRendition specGrp specGrpRef] model.stageLike[camera caption move sound stage tech view] castList] q

Note This class defines the set of chunk- and inter-level elements; it is used in many content models, including those for textual divisions.

---

model.contentPart groups elements which may appear as part of the content element. [*23.5.1. Defining Content Models*]

Module tagdocs — Documentation Elements

Used by alternate content interleave sequence

Members alternate anyElement classRef dataRef elementRef empty interleave macroRef sequence textNode

---

model.correspActionPart groups elements which define the parts (usually names, dates and places) of one action related to the correspondence.

Module tei — The TEI Infrastructure

Used by correspAction

Members model.addressLike[address affiliation email] model.dateLike[date time] model.nameLike[model.nameLike.agent[name orgName persName] model.offsetLike[geogFeat offset] model.persNamePart[addName forename genName nameLink persPronouns roleName surname] model.placeStateLike[model.placeNamePart[bloc country district geogName placeName region

model.div6Like groups sixth-level structural divisions.
Module tei — The TEI Infrastructure
Used by div5
Members div6

---

model.div7Like groups seventh-level structural divisions.
Module tei — The TEI Infrastructure
Used by div6
Members div7

---

model.divBottom groups elements appearing at the end of a text division. [*4.2. Elements Common to All Divisions*]
Module tei — The TEI Infrastructure

Used by body div div1 div2 div3 div4 div5 div6 div7 epilogue figure front group lg list performance prologue table

Members model.divBottomPart[address closer postscript signed trailer] model.divWrapper[argument byline dateline docAuthor docDate epigraph meeting salute]

---

model.divBottomPart groups elements which can occur only at the end of a text division. [*4.6. Title Pages*]

Module tei — The TEI Infrastructure

Used by back model.divBottom postscript

Members address closer postscript signed trailer

---

model.divGenLike groups elements used to represent a structural division which is generated rather than explicitly present in the source.

Module tei — The TEI Infrastructure

Used by body div div1 div2 div3 div4 div5 div6

Members divGen

---

model.divLike groups elements used to represent un-numbered generic structural divisions.

Module tei — The TEI Infrastructure

Used by back body div front lem rdg

Members div

---

model.divPart groups paragraph-level elements appearing directly within divisions. [*1.3. The TEI Class System*]

Module tei — The TEI Infrastructure

Used by lem macro.specialPara macro.specialPara.cmc model.common rdg specGrp

Members model.divPart.spoken[annotationBlock u] model.lLike[l] model.pLike[ab p] eTree forest graph lg listForest sp spGrp tree

Note Note that this element class does not include members of the `model.inter` class, which can appear either within or between paragraph-level items.

---

model.divPart.spoken groups elements structurally analogous to paragraphs within spoken texts. [*8.1. General Considerations and Overview*]

Module spoken — Transcriptions of Speech

Used by model.divPart

Members annotationBlock u

Note Spoken texts may be structured in many ways; elements in this class are typically larger units such as turns or utterances.

---

model.divTop groups elements appearing at the beginning of a text division. [*4.2. Elements Common to All Divisions*]

Module tei — The TEI Infrastructure

Used by body castList div div1 div2 div3 div4 div5 div6 div7 epilogue group lg list performance prologue

B Attribute Classes

B.1 About the Attribute Classes Appendix

This appendix gives you a list of attribute classes and links to the reference pages for them. There are 86 distinctly-named attribute classes in revision 113e933e2 of TEI P5 Version 4.12.0 of the TEI Guidelines.

---

att.anchoring (anchoring) provides attributes for use on annotations, e.g. notes and groups of notes describing the existence and position of an anchor for annotations.

Module tei — The TEI Infrastructure

Members note noteGrp

Attributes

`@anchored` (anchored) indicates whether the copy text shows the exact place of reference for the note.

Status Optional

Datatype teidata.truthValue

Default true

Note In modern texts, notes are usually anchored by means of explicit footnote or endnote symbols. An explicit indication of the phrase or line annotated may however be used instead (e.g. 'page 218, lines 3–4'). The *anchored* attribute indicates whether any explicit location is given, whether by symbol or by prose cross-reference. The value true indicates that such an explicit location is indicated in the copy text; the value false indicates that the copy text does not indicate a specific place of attachment for the note. If the specific symbols used in the copy text at the location the note is anchored are to be recorded, use the *n* attribute.

`@targetEnd` (target end) points to the end of the span to which the note is attached, if the note is not embedded in the text at that point.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note This attribute is retained for backwards compatibility; it may be removed at a subsequent release of the Guidelines. The recommended way of pointing to a span of elements is by means of the `range` function of XPointer, as further described in *17.2.4.6. range()*.

Example

```
<p>(...) tamen reuerendos dominos archiepiscopum et canonicos Leopolienses
necnon episcopum in duplicibus Quatuortemporibus<anchor xml:id="A55234"/>
totaliter expediui...</p>
<!-- elsewhere in the document -->
<noteGrp targetEnd="#A55234">
  <note xml:lang="en"> Quatuor Tempora, so called dry fast days.
  </note>
  <note xml:lang="pl"> Quatuor Tempora, tzw. Suche dni postne.
  </note>
</noteGrp>
```

---

att.ascribed provides attributes for elements representing speech or action that can be ascribed to a specific individual. [*3.3.3. Quotation 8.3. Elements Unique to Spoken Texts*]

Module tei — The TEI Infrastructure

Members att.ascribed.directed[kinesic move pause q said sp spGrp stage u vocal writing] annotationBlock change incident post setting shift

Attributes

`@who` indicates the person, or group of people, to whom the element content is ascribed.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

In the following example from Hamlet, speeches (<sp>) in the body of the play are linked to <role> elements in the <castList> using the *who* attribute.

```
<castItem type="role">
  <role xml:id="Barnardo">Bernardo</role>
</castItem>
<castItem type="role">
  <role xml:id="Francisco">Francisco</role>
  <roleDesc>a soldier</roleDesc>
</castItem>
<!-- ... -->
<sp who="#Barnardo">
  <speaker>Bernardo</speaker>
  <l n="1">Who's there?</l>
</sp>
<sp who="#Francisco">
  <speaker>Francisco</speaker>
  <l n="2">Nay, answer me: stand, and unfold yourself.</l>
</sp>
```

Note For transcribed speech, this will typically identify a participant or participant group; in other contexts, it will point to any identified <person> element.

---

att.ascribed.directed provides attributes for elements representing speech or action that can be directed at a group or individual. [*3.3.3. Quotation 8.3. Elements Unique to Spoken Texts*]

Module tei — The TEI Infrastructure

Members kinesic move pause q said sp spGrp stage u vocal writing

Attributes

- att.ascribed
  - *@who*

`@toWhom` indicates the person, or group of people, to whom a speech act or action is directed.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

In the following example from Mary Pix's The False Friend, speeches (<sp>) in the body of the play are linked to <castItem> elements in the <castList> using the *toWhom* attribute, which is used to specify who the speech is directed to. Additionally, the <stage> includes *toWhom* to indicate the directionality of the action.

```
<castItem type="role">
  <role xml:id="emil">Emilius.</role>
</castItem>
<castItem type="role">
  <role xml:id="lov">Lovisa</role>
</castItem>
<castItem type="role">
  <role xml:id="serv">A servant</role>
</castItem>
<!-- ... -->
<sp who="#emil"
  toWhom="#lov">
```

```
  <speaker>Emil.</speaker>
  <l  n="1">My love!</l>
</sp>
<sp  who="#lov"
  toWhom="#emil">
  <speaker>Lov.</speaker>
  <l  n="2">I have no Witness of my Noble Birth</l>
  <stage  who="emil"
    toWhom="#serv">Pointing to her Woman.</stage>
  <l>But that poor helpless wretch——</l>
</sp>
```

Note To indicate the recipient of written correspondence, use the elements used in section *2.4.6. Correspondence Description*, rather than a *toWhom* attribute.

---

att.breaking provides attributes to indicate whether or not the element concerned is considered to mark the end of an orthographic token in the same way as whitespace. [*3.11.3. Milestone Elements*]

Module tei — The TEI Infrastructure

Members cb gb lb milestone pb

Attributes

`@break` indicates whether or not the element bearing this attribute should be considered to mark the end of an orthographic token in the same way as whitespace.

Status Recommended

Datatype teidata.enumerated

Sample values include **yes** the element bearing this attribute is considered to mark the end of any adjacent orthographic token irrespective of the presence of any adjacent whitespace

no the element bearing this attribute is considered not to mark the end of any adjacent orthographic token irrespective of the presence of any adjacent whitespace

maybe the encoding does not take any position on this issue.

In the following lines from the 'Dream of the Rood', the words *lāðost* and *reord-berendum* each start on one line and continue onto the next.

```
<ab> ...epesa
tome iu icpæs ȝeporden þita heardoſt .
leodum la<lb  break="no"/> ðost ærþan ichim lifes
þeȝ rihtne ȝerymde reord be<lb  break="no"/>
rendum hpæt me þaȝepeorðode þuldres ealdor ofer...
</ab>
```

---

att.calendarSystem provides attributes for indicating calendar systems to which a date belongs. [*3.6.4. Dates and Times 14.4. Dates*]

Module tei — The TEI Infrastructure

Members date docDate origDate time

Attributes

`@calendar` indicates one or more systems or calendars to which the date represented by the content of this element belongs.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Schematron <sch:rule context="tei:*[@calendar]"> <sch:assert test="string-length(

normalize-space(.)) gt 0"> @calendar indicates one or more systems or calendars to which the date represented by the content of this element belongs, but this «sch:name/» element has no textual content.</sch:assert> </sch:rule>

```
He was born on <date  calendar="#gregorian">Feb. 22, 1732</date>
(<date  calendar="#julian"
  when="1732-02-22">Feb. 11, 1731/32,
O.S.</date>).

He was born on <date  calendar="#gregorian #julian"
  when="1732-02-22">Feb. 22, 1732
(Feb. 11, 1731/32, O.S.)</date>.
```

Note Note that the *calendar* attribute declares the calendar system used to interpret the textual content of an element, as it appears on an original source. It does *not* modify the interpretation of the normalization attributes provided by att.datable.w3c, att.datable.iso, or att.datable.custom. Attributes from those first two classes are always interpreted as Gregorian or proleptic Gregorian dates, as per the respective standards on which they are based. The calender system used to interpret the last (att.datable.custom) may be specified with *datingMethod*.

---

att.canonical provides attributes that can be used to associate a representation such as a name or title with canonical information about the object being named or referenced. [*14.1.1. Linking Names and Their Referents*]

Module tei — The TEI Infrastructure

Members att.naming[att.personal[addName eventName forename genName name objectName orgName persName placeName roleName surname] affiliation author birth bloc climate collection country death district editor education event geogFeat geogName institution nationality occupation offset origPlace population pubPlace region repository residence rs settlement socecStatus state terrain trait] actor address authority bibl biblFull biblStruct catDesc correspDesc date distributor docAuthor docTitle faith funder material meeting object objectType post principal publisher relation resp respStmt sponsor term time title unitDecl unitDef

Attributes

`@key` provides an externally-defined means of identifying the entity (or entities) being named, using a coded value of some kind.

Status Optional

Datatype teidata.text

```
<author>
  <name  key="Hugo, Victor (1802-1885)"
    ref="http://www.idref.fr/026927608">Victor Hugo</name>
</author>
```

Note The value may be a unique identifier from a database, or any other externally-defined string identifying the referent. No particular syntax is proposed for the values of the *key* attribute, since its form will depend entirely on practice within a given project.

`@ref` (reference) provides an explicit means of locating a full definition or identity for the entity being named by means of one or more URIs.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

```
<name ref="http://viaf.org/viaf/109557338"
  type="person">Seamus Heaney</name>
```

Note The value must point directly to one or more XML elements or other resources by means of one or more URIs, separated by whitespace. If more than one is supplied the implication is that the name identifies several distinct entities.

Example In this contrived example, a canonical reference to the same organisation is provided in four different ways.

```
<author n="1">
  <name ref="http://nzetc.victoria.ac.nz/tm/scholarly/name-427308.html"
    type="organisation">New Zealand Parliament, Legislative Council</name>
</author>

<author n="2">
  <name ref="nzvn:427308"
    type="organisation">New Zealand Parliament, Legislative Council</name>
</author>

<author n="3">
  <name ref="./named_entities.xml#o427308"
    type="organisation">New Zealand Parliament, Legislative Council</name>
</author>

<author n="4">
  <name key="name-427308"
    type="organisation">New Zealand Parliament, Legislative Council</name>
</author>
```

The first presumes the availability of an internet connection and a processor that can resolve a URI (most can). The second requires, in addition, a <prefixDef> that declares how the `nzvm` prefix should be interpreted. The third does not require an internet connection, but does require that a file named named_entities.xml be in the same directory as the TEI document. The fourth requires that an entire external system for key resolution be available.

Note The *key* attribute is more flexible and general-purpose, but its use in interchange requires that documentation about how the key is to be resolved be sent to the recipient of the TEI document. In contrast values of the *ref* attribute are resolved using the widely accepted protocols for a URI, and thus less documentation, if any, is likely required by the recipient in data interchange.

These guidelines provide no semantic basis or suggested precedence when both *key* and *ref* are provided. For this reason simultaneous use of both is not recommended unless documentation explaining the use is provided, probably in an ODD customization, for interchange.

---

att.citeStructurePart provides attributes for selecting particular elements within a document.

Module header — The TEI Header

Members citeData citeStructure

Attributes

`@use` (use) supplies an XPath selection pattern using the syntax defined in ?. The XPath pattern is relative to the context given in *match*, which will either be a sibling attribute in the case of <citeStructure> or on the parent <citeStructure> in the case of <citeData>.

Status Required

Datatype teidata.xpath

att.citing provides attributes for specifying the specific part of a bibliographic item being cited. [*1.3.1. Attribute Classes*]

Module tei — The TEI Infrastructure

Members biblScope citedRange

Attributes

`@unit` identifies the unit of information conveyed by the element.
Status Optional
Datatype teidata.enumerated
Suggested values include: **volume** (volume) the element contains a volume number.
issue the element contains an issue number, or volume and issue numbers.
page (page) the element contains a page number or page range.
line the element contains a line number or line range.
chapter (chapter) the element contains a chapter indication (number and/or title)
part the element identifies a part of a book or collection.
column the element identifies a column.
entry the element identifies an entry number or label in a list of entries.

`@from` specifies the starting point of the range of units indicated by the *unit* attribute.
Status Optional
Datatype teidata.word

`@to` specifies the end-point of the range of units indicated by the *unit* attribute.
Status Optional
Datatype teidata.word

---

att.cmc (computer-mediated communication) provides attributes categorizing how the element content was created in a CMC environment.

Module tei — The TEI Infrastructure

</post>
```

---

att.combinable provides attributes indicating how multiple references to the same object in a schema should be combined.

Module tagdocs — Documentation Elements

Members att.identified[attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec] defaultVal remarks valDesc valItem valList

Attributes
- att.deprecated
  - *@validUntil*

`@mode` specifies the effect of this declaration on its parent object.

Status Optional

Datatype teidata.enumerated

Legal values are: **add** this declaration is part of the current definitions.[Default]

delete the object with the same identifier (and namespace in the case of an element or attribute) as the current one is no longer part of the current definitions

change this declaration changes the object of the same identifier (and namespace in the case of an element or attribute) in the current definition

replace this declaration replaces the object with the same identifier (and namespace in the case of an element or attribute) in the current definition.

An ODD processor should handle the values for *mode* as follows:

Note **add** the object should be created (processing any children in add mode); raise an error if the object has an identifier and an object with the same identifier (and namespace in the case of an element or attribute) already exists.

replace use this object in preference to any existing object with the same identifier (and namespace in the case of an element or attribute), and ignore any children of that object; process any new children in replace mode

delete do not process this object or any existing object with the same identifier (and namespace in the case of an element or attribute); the element carrying this attribute must be empty: raise an error if there are any children

change process this object and its children, replacing only those components of an existing object of the same type with the same identifier (and namespace in case of an element or attribute) that are explicitly specified. This will change only those existing attribute values and child elements that appear both in the original specification and in the new specification. Other children from the original specification will be preserved.

---

att.coordinated provides attributes that can be used to position their parent element within a two and three dimensional coordinate system.

Module transcr — Representation of Primary Sources

Members line path surface zone

Attributes

`@start` indicates the element within a transcription of the text containing at least the start of the writing represented by this zone or surface.

Status Optional

Datatype teidata.pointer

`@ulx` gives the x coordinate value for the upper left corner of a rectangular space.
Status Optional

Datatype teidata.numeric

`@uly` gives the y coordinate value for the upper left corner of a rectangular space.
Status Optional

Datatype teidata.numeric

`@lrx` gives the x coordinate value for the lower right corner of a rectangular space.
Status Optional

Datatype teidata.numeric

`@lry` gives the y coordinate value for the lower right corner of a rectangular space.
Status Optional

Datatype teidata.numeric

`@points` identifies a two or three dimensional area by means of a series of pairs of numbers, each of which gives the x,y, or z coordinates of a point on a line enclosing the area.
Status Optional

Datatype 3–∞ occurrences of teidata.point separated by whitespace

---

att.cReferencing provides attributes that may be used to supply a *canonical reference* as a means of identifying the target of a pointer.

Module tei — The TEI Infrastructure

Members gloss ptr ref term

Attributes

`@cRef` (canonical reference) specifies the destination of the pointer by supplying a canonical reference expressed using the scheme defined in a <refsDecl> element in the TEI header.
Status Optional

Datatype teidata.text

Note The value of *cRef* should be constructed so that when the algorithm for the resolution of canonical references (described in section *17.2.5. Canonical References*) is applied to it the result is a valid URI reference to the intended target.

The <refsDecl> to use may be indicated with the *decls* attribute.

Currently these Guidelines only provide for a single canonical reference to be encoded on any given <ptr> element.

---

att.damaged provides attributes describing the nature of any physical damage affecting a reading. [*12.3.3.1. Damage, Illegibility, and Supplied Text 1.3.1. Attribute Classes*]

Module tei — The TEI Infrastructure

Members damage damageSpan

Attributes
- att.dimensions
  - *@unit*
  - *@quantity*
  - *@extent*
  - *@precision*
  - *@scope*

  - att.ranging
    - *@atLeast*
    - *@atMost*
    - *@min*
    - *@max*
    - *@confidence*
- att.written
  - *@hand*

`@agent` categorizes the cause of the damage, if it can be identified.
Status Optional
Datatype teidata.enumerated
Sample values include: **rubbing** damage results from rubbing of the leaf edges
mildew damage results from mildew on the leaf surface
smoke damage results from smoke

`@degree` provides a coded representation of the degree of damage, either as a number between 0 (undamaged) and 1 (very extensively damaged), or as one of the codes high, medium, low, or unknown. The <damage> element with the *degree* attribute should only be used where the text may be read with some confidence; text supplied from other sources should be tagged as <supplied>.
Status Optional
Datatype teidata.probCert
Note The <damage> element is appropriate where it is desired to record the fact of damage although this has not affected the readability of the text, for example a weathered inscription. Where the damage has rendered the text more or less illegible either the <unclear> tag (for partial illegibility) or the <gap> tag (for complete illegibility, with no text supplied) should be used, with the information concerning the damage given in the attribute values of these tags. See section *12.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of the use of these tags in particular circumstances.

`@group` assigns an arbitrary number to each stretch of damage regarded as forming part of the same physical phenomenon.
Status Optional
Datatype teidata.count

---

att.datable provides attributes for normalization of elements that contain dates, times, or datable events. [*3.6.4. Dates and Times 14.4. Dates*]

Module tei — The TEI Infrastructure

Members att.gaijiProp[localProp unicodeProp unihanProp] acquisition affiliation age altIdentifier application author binding birth bloc change climate conversion country creation custEvent date death district docDate editor education event eventName faith floruit funder gender geogFeat geogName idno langKnowledge langKnown licence location mapping meeting name nationality objectName occupation offset org orgName origDate origPlace origin persName persPronouns person place placeName population post precision principal provenance region relation residence resp seal settlement sex socecStatus sponsor stamp state terrain time title trait unitDecl unitDef

Attributes
- att.datable.custom
  - *@when-custom*

- *@notBefore-custom*
- *@notAfter-custom*
- *@from-custom*
- *@to-custom*
- *@datingPoint*
- *@datingMethod*

- att.datable.iso
  - *@when-iso*
  - *@notBefore-iso*

  - *@from-iso*
  - *@to-iso*
- att.datable.w3c
  - *@when*
  - *@notBefore*
  - *@notAfter*
  - *@from*
  - *@to*

`@period` supplies pointers to one or more definitions of named periods of time (typically <category>s, <date>s, or <event>s) within which the datable item is understood to have occurred.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

This 'superclass' provides attributes that can be used to provide normalized values of temporal information. By default, the attributes from the `att.datable.w3c` class are provided. If the module for names & dates is loaded, this class also provides attributes from the `att.datable.iso` and `att.datable.custom` classes. In general, the possible values of attributes restricted to the W3C datatypes form a subset of those values available via the ISO 8601 standard. However, the greater expressiveness of the ISO datatypes may not be needed, and there exists much greater software support for the W3C datatypes.

---

att.datable.custom

Name `att.datable.custom`

Description provides attributes for normalization of elements that contain datable events to a custom dating system (i.e. other than the Gregorian used by W3 and ISO). [*14.4. Dates*]

Module namesdates — Names, Dates, People, and Places

Members att.datable[att.gaijiProp[localProp unicodeProp unihanProp] acquisition affiliation age altIdentifier application author binding birth bloc change climate conversion country creation custEvent date death district docDate editor education event eventName faith floruit funder gender geogFeat geogName idno langKnowledge langKnown licence location mapping meeting name nationality objectName occupation offset org orgName origDate origPlace origin persName persPronouns person place placeName population post precision principal provenance region relation residence resp seal settlement sex socecStatus sponsor stamp state terrain time title trait unitDecl unitDef]

Attributes

`@when-custom` supplies the value of a date or time in some custom standard form.
Status Optional
Datatype 1–∞ occurrences of teidata.word separated by whitespace

The following are examples of custom date or time formats that are *not* valid ISO or W3C format normalizations, normalized to a different dating system

```
<p>Alhazen died in Cairo on the
<date when="1040-03-06"
   when-custom="431-06-12"> 12th day of Jumada t-Tania, 430 AH
 </date>.</p>
<p>The current world will end at the
<date when="2012-12-21"
   when-custom="13.0.0.0.0">end of B'ak'tun 13</date>.</p>
<p>The Battle of Meggidu
(<date when-custom="Thutmose_III:23">23rd year of reign of
Thutmose III</date>).</p>
<p>Esidorus bixit in pace annos LXX plus minus sub
<date when-custom="Ind:4-10-11">die XI mensis Octobris
indictione IIII</date>
</p>Not all custom date formulations will have Gregorian
equivalents.The when-custom attribute and other custom dating
are not constrained to a datatype by the TEI, but individual
projects are recommended to regularize and document their dating
formats.
```

`@notBefore-custom` specifies the earliest possible date for the event in some custom standard form.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

`@notAfter-custom` specifies the latest possible date for the event in some custom standard form.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

`@from-custom` indicates the starting point of the period in some custom standard form.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

```
<event xml:id="FIRE1"
  datingMethod="#julian"
  from-custom="1666-09-02"
  to-custom="1666-09-05">
  <head>The Great Fire of London</head>
  <p>The Great Fire of London burned through a large part
     of the city of London.</p>
</event>
```

`@to-custom` indicates the ending point of the period in some custom standard form.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

`@datingPoint` supplies a pointer to some location defining a named point in time with reference to which the datable item is understood to have occurred.

Status Optional

Datatype teidata.pointer

`@datingMethod` supplies a pointer to a <calendar> element or other means of interpreting the values of the custom dating attributes.

Status Optional

Datatype teidata.pointer

```
Contayning the Originall, Antiquity, Increaſe, Moderne
eſtate, and deſcription of that Citie, written in the yeare
<date when-custom="1598"
  calendar="#julian"
  datingMethod="#julian">1598</date>. by Iohn Stow
```

Citizen of London.In this example, the *calendar* attribute points to a <calendar> element for the Julian calendar, specifying that the text content of the <date> element is a Julian date, and the *datingMethod* attribute also points to the Julian calendar to indicate that the content of the *when-custom* attribute value is Julian too.

```
<date when="1382-06-28"
  when-custom="6890-06-20"
  datingMethod="#creationOfWorld"> μηνὶ Ἰουνίου εἰς <num>κ</num>
ἔτους <num>ϛωϡ</num>
</date>In this example, a date is given in a Mediaeval text
measured 'from the creation of the world', which is normalized
(in when) to the Gregorian date, but is also normalized (in
when-custom) to a machine-actionable, numeric version of the
date from the Creation.
```

Note Note that the *datingMethod* attribute (unlike *calendar* defined in att.datable) defines the calendar or dating system to which the date described by the parent element is normalized (i.e. in the *when-custom* or other *X-custom* attributes), *not* the calendar of the original date in the element.

---

att.datable.iso provides attributes for normalization of elements that contain datable events using the ISO 8601:2004 standard. [*3.6.4. Dates and Times 14.4. Dates*]

Attributes

`@when-iso` supplies the value of a date or time in a standard form.

Status Optional

Datatype teidata.temporal.iso

The following are examples of ISO date, time, and date & time formats that are *not* valid W3C format normalizations.

```
<date when-iso="1996-09-24T07:25+00">Sept. 24th, 1996 at 3:25
in the morning</date>
<date when-iso="1996-09-24T03:25-04">Sept. 24th, 1996 at 3:25
in the morning</date>
<time when-iso="1999-01-04T20:42-05">4 Jan 1999 at 8:42
pm</time>
<time when-iso="1999-W01-1T20,70-05">4 Jan 1999 at 8:42
pm</time>
<date when-iso="2006-05-18T10:03">a few minutes after ten in
the morning on Thu 18 May</date>
<time when-iso="03:00">3 A.M.</time>
<time when-iso="14">around two</time>
<time when-iso="15,5">half past three</time>All of the examples
of the when attribute in the att.datable.w3c class are also
valid with respect to this attribute.
```

```
He likes to be punctual. I said <q>
  <time when-iso="12">around noon</time>
```

```
</q>, and he showed up at <time  when-iso="12:00:00">12
O'clock</time> on the dot.The second occurrence of <time> could
have been encoded with the when attribute, as 12:00:00 is a
valid time with respect to the W3C XML Schema Part 2: Datatypes
Second Edition specification. The first occurrence could not.
```

`@notBefore-iso` specifies the earliest possible date for the event in standard form, e.g. yyyy-mm-dd.
Status Optional
Datatype teidata.temporal.iso

`@notAfter-iso` specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.
Status Optional
Datatype teidata.temporal.iso

`@from-iso` indicates the starting point of the period in standard form.
Status Optional
Datatype teidata.temporal.iso

`@to-iso` indicates the ending point of the period in standard form.
Status Optional
Datatype teidata.temporal.iso

The value of these attributes should be a normalized representation of the date, time, or combined date & time intended, in any of the standard formats specified by ISO 8601:2004, using the Gregorian calendar.

If both *when-iso* and *dur-iso* are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. That is,

```
<date  when-iso="2007-06-01"  dur-iso="P8D"/>
```

indicates the same time period as

```
<date  when-iso="2007-06-01/P8D"/>
```

In providing a 'regularized' form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

---

att.datable.w3c

`att.datable.w3c` provides attributes for normalization of elements that contain datable events conforming to the W3C XML Schema Part 2: Datatypes Second Edition. [*3.6.4. Dates and Times 14.4. Dates*]

Schematron <sch:rule context="tei:*[@to]"> <sch:report test="@notAfter" role="nonfatal">The @to and @notAfter attributes cannot be used together.</sch:report> </sch:rule>

Example

```
<date  from="1863-05-28"  to="1863-06-01">28 May through 1 June 1863</date>
```

Note The value of these attributes should be a normalized representation of the date, time, or combined date & time intended, in any of the standard formats specified by XML Schema Part 2: Datatypes Second Edition, using the Gregorian calendar.

The most commonly-encountered format for the date portion of a temporal attribute is `yyyy-mm-dd`, but `yyyy`, `--mm`, `---dd`, `yyyy-mm`, or `--mm-dd` may also be used. For the time part, the form `hh:mm:ss` is used.

Note that this format does not currently permit use of the value 0000 to represent the year 1 BCE; instead the value -0001 should be used.

---

att.datcat provides attributes that are used to align XML elements or attributes with the appropriate Data Categories (DCs) defined by an external taxonomy, in this way establishing the identity of information containers and values, and providing means of interpreting them. [*10.5.2. Lexical View 19.3. Other Atomic Feature Values*]

Module tei — The TEI Infrastructure

Members att.lexicographic[case colloc def entryFree etym form gen gram gramGrp hom hyph iType lang lbl mood number oRef orth pRef per pos pron sense subc syll tns usg xr] att.segLike[c cl m pc phr s seg w] binary category f fDecl fs fsDecl numeric string symbol tagUsage taxonomy

Attributes

`@datcat` provides a pointer to a definition of, and/or general information about, (a) an information container (element or attribute) or (b) a value of an information container (element content or attribute value), by referencing an external taxonomy or ontology. If *valueDatcat* is present in the immediate context, this attribute takes on role (a), while *valueDatcat* performs role (b).
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@valueDatcat` provides a definition of, and/or general information about a value of an information container (element content or attribute value), by reference to an external taxonomy or ontology. Used especially where a contrast with *datcat* is needed.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@targetDatcat` provides a definition of, and/or general information about, information structure of an object referenced or modeled by the containing element, by reference to an external taxonomy or ontology. This attribute has the characteristics of the *datcat* attribute, except that it addresses not its containing element, but an object that is being referenced or modeled by its containing element.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Example The example below presents the TEI encoding of the name-value pair `<part of speech, common noun>`, where the name (key) 'part of speech' is abbreviated as 'POS', and the value, 'common noun' is symbolized by 'NN'. The entire name-value pair is encoded by means of the element <f>. In TEI XML, that element acts as the container, labeled with the *name* attribute. Its contents may be complex or simple. In the case at hand, the content is the symbol 'NN'.The *datcat* attribute relates the feature *name* (i.e., the key) to the data category 'part of speech', while the attribute *valueDatcat* relates the feature *value* to the data category *common noun*. Both these data categories should be defined in an external and preferably open reference taxonomy or ontology.

```
<fs>
  <f  name="POS"
    datcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3">
    <symbol  valueDatcat="http://hdl.handle.net/11459/CCR_C-1256_7ec6083c-23d4-224d-6f94-eecbe
      value="NN"/>
  </f>
<!-- ... -->
</fs>
```

'NN' is the symbol for common noun used e.g. in the CLAWS-7 tagset defined by the University Centre

for Computer Corpus Research on Language at the University of Lancaster. The very same data category used for tagging an early version of the British National Corpus, and coming from the BNC Basic (C5) tagset, uses the symbol 'NN0' (rather than 'NN'). Making these values semantically interoperable would be extremely difficult without a human expert if they were not anchored in a single point of an established reference taxonomy of morphosyntactic data categories. In the case at hand, the string 'http://hdl.handle.net/11459/CCR_C-1256_7ec6083c-23d4-224d-6f94-eecbe6861545' is both a persistent identifier of the data category in question, as well as a pointer to a shared definition of *common noun*.While the symbols 'NN', 'NN0', and many others (often coming from languages other than English) are implicitly members of the container category 'part of speech', it is sometimes useful not to rely on such an implicit relationship but rather use an explicit identifier for that data category, to distinguish it from other morphosyntactic data categories, such as gender, tense, etc. For that purpose, the above example uses the *datcat* attribute to reference a definition of *part of speech*. The reference taxonomy in this example is the CLARIN Concept Registry.If the feature structure markup exemplified above is to be repeated many times in a single document, it is much more efficient to gather the persistent identifiers in a single place and to only reference them, implicitly or directly, from feature structure markup. The following example is much more concise than the one above and relies on the concepts of feature structure declaration and feature value library, discussed in chapter *19. Feature Structures*.

```
<fs>
  <f  name="POS"  fVal="#commonNoun"/>
<!-- ... -->
</fs>
```

The assumption here is that the relevant feature values are collected in a place that the annotation document in question has access to — preferably, a single document per linguistic resource, for example an <fsdDecl> that is XIncluded as a sibling of <text> or a child of <encodingDesc>; a <taxonomy> available resource-wide (e.g., in a shared header) is also an option.The example below presents an <fvLib> element that collects the relevant feature values (most of them omitted). At the same time, this example shows one way of encoding a *tagset*, i.e., an established inventory of values of (in the case at hand) morphosyntactic categories.

```
<fvLib  n="POS values">
  <symbol  xml:id="commonNoun"  value="NN"
    datcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3"/>
  <symbol  xml:id="properNoun"  value="NP"
    datcat="http://hdl.handle.net/11459/CCR_C-1371_fbebd9ec-a7f4-9a36-d6e9-88ee16b944ae"/>
<!-- ... -->
</fvLib>
```

Note that these Guidelines do not prescribe a specific choice between *datcat* and *valueDatcat* in such cases. The former is the generic way of referencing a data category, whereas the latter is more specific, in that it references a data category that represents a value. The choice between them comes into play where a single element — or a tight element complex, such as the <f>/<symbol> complex illustrated above — make it necessary or useful to distinguish between the container data category and its value.

Example In the context of dictionaries designed with semantic interoperability in mind, the following example ensures that the <pos> element is interpreted as the same information container as in the case of the example of <f name="POS"> above.

```
<gramGrp>
  <pos  datcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3"
    valueDatcat="http://hdl.handle.net/11459/CCR_C-1256_7ec6083c-23d4-224d-6f94-eecbe6861545">
</gramGrp>
```

Efficiency of this type of interoperable markup demands that the references to the particular data categories should best be provided in a single place within the dictionary (or a single place within the project), rather than being repeated inside every entry. For the container elements, this can be achieved at the level of <tagUsage>, although here, the *valueDatcat* attribute should be used, because it is not the

<tagUsage> element that is associated with the relevant data category, but rather the element <pos> (or <case>, etc.) that is described by <tagUsage>:

```
<tagsDecl  partial="true">
<!-- ... -->
  <namespace  name="http://www.tei-c.org/ns/1.0">
    <tagUsage  gi="pos"
      targetDatcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3
the part of speech.</tagUsage>
    <tagUsage  gi="case"
      targetDatcat="http://hdl.handle.net/11459/CCR_C-1840_9f4e319c-f233-6c90-9117-7270e215f03
information about the grammatical case that the described form is inflected
for.</tagUsage>
<!-- ... -->
  </namespace>
</tagsDecl>
```

Another possibility is to shorten the URIs by means of the <prefixDef> mechanism, as illustrated below:

```
<listPrefixDef>
  <prefixDef  ident="ccr"  matchPattern="pos"
    replacementPattern="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f
  <prefixDef  ident="ccr"  matchPattern="adj"
    replacementPattern="http://hdl.handle.net/11459/CCR_C-1230_23653c21-fca1-edf8-fd7c-3df2d64
</listPrefixDef>
<!-- ... -->
<entry>
<!--...-->
  <form>
    <orth>isotope</orth>
  </form>
  <gramGrp>
    <pos  datcat="ccr:pos"
      valueDatcat="ccr:adj">adj</pos>
  </gramGrp>
<!--...-->
</entry>
```

This mechanism creates implications that are not always wanted, among others, in the case at hand, suggesting that the identifiers ‘pos’ and ‘adj’ belong to a namespace associated with the CLARIN Concept Repository (CCR), whereas that is solely a shorthand mechanism whose scope is the current resource. Documenting this clearly in the header of the dictionary is therefore advised.Yet another possibility is to associate the information about the relationship between a TEI markup element and the data category that it is intended to model already at the level of modeling the dictionary resource, that is, at the level of the ODD, in the <equiv> element that is a child of <elementSpec> or <attDef>.

Example The <taxonomy> element is a handy tool for encoding taxonomies that are later referenced by `att.datcat` attributes, but it can also act as an intermediary device, for example holding a fragment of an external taxonomy (or ‘flattening’ an external ontology) that is relevant to the project or document at hand. (It is also imaginable that, for the purpose of the project at hand, the local <taxonomy> element combines vocabularies that originate from more than one external taxonomy or ontology.) In such cases, the <taxonomy> creates a local layer of indirection: the `att.datcat` attributes internal to the resource may reference the <category> elements stored in the header (as well as the <taxonomy> element itself), whereas these same <category> and <taxonomy> elements use `att.datcat` attributes to reference the original taxonomy or ontology.

```
<encodingDesc>
<!-- ... -->
  <classDecl>
<!-- ... -->
    <taxonomy  xml:id="UD-SYN"
      datcat="https://universaldependencies.org/u/dep/index.html">
      <desc>
        <term>UD syntactic relations</term>
      </desc>
      <category  xml:id="acl"
        valueDatcat="https://universaldependencies.org/u/dep/acl.html">
        <catDesc>
          <term>acl</term>: Clausal modifier of noun (adjectival
clause)</catDesc>
      </category>
      <category  xml:id="acl_relcl"
        valueDatcat="https://universaldependencies.org/u/dep/acl-relcl.html">
        <catDesc>
          <term>acl:relcl</term>: relative clause modifier</catDesc>
      </category>
      <category  xml:id="advcl"
        valueDatcat="https://universaldependencies.org/u/dep/advcl.html">
        <catDesc>
          <term>advcl</term>: Adverbial clause modifier</catDesc>
      </category>
<!-- ... -->
    </taxonomy>
  </classDecl>
</encodingDesc>
```

The above fragment was excerpted from the GB subset of the ParlaMint project in April 2023, and enriched with `att.datcat` attributes for the purpose of illustrating the mechanism described here.Note that, in the ideal case, the values of `att.datcat` attributes should be persistent identifiers, and that the addressing scheme of Universal Dependencies is treated here as persistent for the sake of illustration. Note also that the contrast between *datcat* used on <taxonomy> on the one hand, and the *valueDatcat* used on <category> on the other, is not mandatory: both kinds of relations could be encoded by means of the generic *datcat* attribute, but using the former for the container and the latter for the content is more user-friendly.

Example The *targetDatcat* attribute is designed to be used in, e.g., feature structure declarations, and is analogous to the *targetLang* attribute of the `att.pointing` class, in that it describes the object that is being referenced, rather than the referencing object.

```
<fDecl  name="POS"
  targetDatcat="http://hdl.handle.net/11459/CCR_C-396_5a972b93-2294-ab5c-a541-7c344c5f26c3">
  <fDescr>part of speech (morphosyntactic category)</fDescr>
  <vRange>
    <vAlt>
      <symbol  value="NN"
        datcat="http://hdl.handle.net/11459/CCR_C-1256_7ec6083c-23d4-224d-6f94-eecbe6861545"/>
      <symbol  value="NP"
        datcat="http://hdl.handle.net/11459/CCR_C-1371_fbebd9ec-a7f4-9a36-d6e9-88ee16b944ae"/>
<!-- ... -->
    </vAlt>
  </vRange>
</fDecl>
```

Above, the <fDecl> uses *targetDatcat*, because if it were to use *datcat*, it would be asserting that it is an

instance of the container data category *part of speech*, whereas it is not — it models a container (<f>) that encodes a part of speech. Note also that it is the <f> that is modeled above, not its values, which are used as direct references to data categories; hence the use of *datcat* in the <symbol> element.

Example The `att.datcat` attributes can be used for any sort of taxonomies. The example below illustrates their usefulness for describing usage domain labels in dictionaries on the example of the *Diccionario da Lingua Portugueza* by António de Morais Silva, retro-digitised in the MORDigital project.

```
<!-- in the dictionary header --><encodingDesc>
  <classDecl>
    <taxonomy  xml:id="domains">
<!--...-->
     <category  xml:id="domain.medical_and_health_sciences">
       <catDesc  xml:lang="en">Medical and Health Sciences</catDesc>
       <catDesc  xml:lang="pt">Ciências Médicas e da Saúde</catDesc>
       <category  xml:id="domain.medical_and_health_sciences.medicine"
         valueDatcat="https://vocabs.rossio.fcsh.unl.pt/pub/morais_domains/pt/page/0025">
         <catDesc  xml:lang="en">
           <term>Medicine</term>
           <gloss>
<!--...-->
           </gloss>
         </catDesc>
         <catDesc  xml:lang="pt">
           <term>Medicina</term>
           <gloss>
<!--...-->
           </gloss>
         </catDesc>
       </category>
     </category>
<!--...-->
    </taxonomy>
  </classDecl>
</encodingDesc>
<!--
inside an <entry> element: -->
<usg  type="domain"
  valueDatcat="#domain.medical_and_health_sciences.medicine">Med.</usg>
```

In the Morais dictionary, the relevant domain labels are in the header, getting referenced inside the dictionary, from <usg> elements. The vocabulary used for dictionary-internal labelling is in turn anchored in the MorDigital controlled vocabulary service of the NOVA University of Lisbon – School of Social Sciences and Humanities (NOVA FCSH).

Note The TEI Abstract Model can be expressed as a hierarchy of attribute-value matrices (AVMs) of various types and of various levels of complexity, nested or grouped in various ways. At the most abstract level, an AVM consists of an information container and the value (contents) of that container.

A simple example of an XML serialization of such structures is, on the one hand, the opening and closing tags that delimit and name the container, and, on the other, the content enclosed by the two tags that constitues the value. An analogous example is an attribute name and the value of that attribute.

In a TEI XML example of two equivalent serializations expressing the name-value pair `<part-of-speech,common-noun>`, namely `<pos>commonNoun</pos>` and `pos="common-noun"`, one would classify the element <pos> and the attribute *pos* as containers (mapping onto the first member of the relevant name-value pair), while the character data content of <pos> or the value of *pos* would be seen as mapping onto the second member of the pair.

The `att.datcat` class provides means of addressing the containers and their values, while at the same time providing a way to interpret them in the context of external taxonomies or ontologies.

Aligning e.g. both the <pos> element and the *pos* attribute with the same value of an external reference point (i.e., an entry in an agreed taxonomy) affirms the identity of the concept serialised by both the element container and the attribute container, and optionally provides a definition of that concept (in the case at hand, the concept *part of speech*).

The value of the `att.datcat` attributes should be a PID (persistent identifier) that points to a specific — and, ideally, shared — taxonomy or ontology. Among the resources that can, to a lesser or greater extent, be used as inventories of (more or less) standardized linguistic categories are the GOLD ontology, CLARIN CCR, OLiA, or TermWeb's DatCatInfo, and also the Universal Dependencies inventory, on the assumption that its URIs are going to persist. It is imaginable that a project may choose to address a local taxonomy store instead, but this risks losing the advantage of interchangeability with other projects.

Historically, *datcat* and *valueDatcat* originate from the (now obsolete) ISO 12620:2009 standard, describing the data model and procedures for a Data Category Registry (DCR). The current version of that standard, ISO 12620-1, does not standardize the serialization of pointers, merely mentioning the TEI `att.datcat` as an example.

Note that no constraint prevents the occurrence of a combination of `att.datcat` attributes: the <fDecl> element, which is a natural bearer of the *targetDatcat* attribute, is an instance of a specific modeling element, and, in principle, could be semantically fixed by an appropriate reference taxonomy of modeling devices.

---

att.declarable provides attributes for those elements in the TEI header which may be independently selected by means of the special purpose *decls* attribute. [*16.3. Associating Contextual Information with a Text*]

Module tei — The TEI Infrastructure

Members availability bibl biblFull biblStruct broadcast correction correspDesc editorialDecl equipment geoDecl hyphenation interpretation langUsage listApp listBibl listEvent listNym listObject listOrg listPerson listPlace metDecl normalization particDesc projectDesc punctuation quotation recording refsDecl samplingDecl scriptStmt segmentation seriesStmt settingDesc sourceDesc stdVals styleDefDecl textClass textDesc xenoData

Attributes

`@default` indicates whether or not this element is selected by default when its parent is selected.
Status Optional
Datatype teidata.truthValue
Legal values are: **true** This element is selected if its parent is selected
false This element can only be selected explicitly, unless it is the only one of its kind, in which case it is selected if its parent is selected.[Default]

The rules governing the association of declarable elements with individual parts of a TEI text are fully defined in chapter *16.3. Associating Contextual Information with a Text*. Only one element of a particular type may have a *default* attribute with a value of true.

---

att.declaring provides attributes for elements which may be independently associated with a particular declarable element within the header, thus overriding the inherited default for that element. [*16.3. Associating Contextual Information with a Text*]

Module tei — The TEI Infrastructure

Members ab back body div div1 div2 div3 div4 div5 div6 div7 facsimile floatingText front geo gloss graphic group lg listAnnotation media msDesc object p ptr ref sourceDoc standOff surface surfaceGrp term text u

Attributes

`@decls` (declarations) identifies one or more *declarable elements* within the header, which are understood to apply to the element bearing this attribute and its content.
Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

The rules governing the association of declarable elements with individual parts of a TEI text are fully defined in chapter *16.3. Associating Contextual Information with a Text*.

---

att.deprecated provides attributes indicating how a deprecated feature will be treated in future releases.

Module tagdocs — Documentation Elements

Members att.combinable[att.identified[attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec] defaultVal remarks valDesc valItem valList]

Attributes

`@validUntil` provides a date before which the construct being defined will not be removed.

Status Optional

Datatype date

Schematron <sch:rule context="tei:*[@validUntil]"> <sch:let name="advance_warning_period" value="current-date() + xs:dayTimeDuration('P60D')"/> <sch:let name="me_phrase" value="if (@ident) then concat('The ', @ident) else concat('This ', local-name(.), ' of ', ancestor::tei:*[@ident][1]/@ident)"/> <sch:assert test="@validUntil cast as xs:date ge current-date()"> <sch:value-of select="concat($me_phrase, ' construct is outdated (as of ', @validUntil, '); ODD processors may ignore it, and its use is no longer supported.')"/> </sch:assert> <sch:assert role="warning" test="@validUntil cast as xs:date ge $advance_warning_period"> <sch:value-of select="concat($me_phrase, ' construct becomes outdated on ', @validUntil, '.')"/> </sch:assert> </sch:rule>

Schematron <sch:rule context="tei:*[@validUntil][not(self::tei:valDesc | self::tei:valList | self::tei:defaultVal | self::tei:remarks)]"> <sch:assert test="child::tei:desc[@type eq 'deprecationInfo']"> A deprecated construct should include, whenever possible, an explanation, but this <sch:value-of select="name(.)"/> does not have a child <desc type="deprecationInfo">.</sch:assert> </sch:rule>

Note The value of this attribute should represent a date (in standard `yyyy-mm-dd` format) which is later than the date on which the attribute is added to an ODD. Technically, this attribute asserts only the intent to leave a construct in future releases of the markup language being defined up to at least the specified date, and makes no assertion about what happens past that date. In practice, the expectation is that the construct will be removed from future releases of the markup language being defined sometime shortly after the *validUntil* date.

An ODD processor will typically not process a specification element which has a *validUntil* date that is in the past. An ODD processor will typically warn users about constructs which have a *validUntil* date that is in the future. E.g., the documentation for such a construct might include the phrase *warning: deprecated* in red.

---

att.dimensions provides attributes for describing the size of physical objects.

Module tei — The TEI Infrastructure

Members att.damaged[damage damageSpan] add addSpan age birth date death del delSpan depth dim dimensions ellipsis ex floruit gap geogFeat height mod offset origDate population redo restore retrace secl space state subst substJoin supplied surplus time trait unclear undo width

Attributes

- att.ranging
  - *@atLeast*
  - *@atMost*

- *@min*
- *@max*
- *@confidence*

`@unit` names the unit used for the measurement
Status Optional
Datatype teidata.enumerated
Suggested values include: **cm** (centimetres)
mm (millimetres)
in (inches)
line lines of text
char (characters) characters of text

`@quantity` specifies the length in the units specified
Status Optional
Datatype teidata.numeric

`@extent` indicates the size of the object concerned using a project-specific vocabulary combining quantity and units in a single string of words.
Status Optional
Datatype teidata.text

```
<gap extent="5 words"/>
<height extent="half the page"/>
```

`@precision` characterizes the precision of the values specified by the other attributes.
Status Optional
Datatype teidata.certainty

`@scope` where the measurement summarizes more than one observation, specifies the applicability of this measurement.
Status Optional
Datatype teidata.enumerated
Sample values include: **all** measurement applies to all instances.
most measurement applies to most of the instances inspected.
range measurement applies to only the specified range of instances.

---

att.divLike provides attributes common to all elements which behave in the same way as divisions. [*4. Default Text Structure*]

Module tei — The TEI Infrastructure
Members div div1 div2 div3 div4 div5 div6 div7 lg spGrp
Attributes
- att.fragmentable
  - *@part*
- att.metrical
  - *@met*
  - *@real*
  - *@rhyme*

`@org` (organization) specifies how the content of the division is organized.
Status Optional
Datatype teidata.enumerated
Legal values are: **composite** no claim is made about the sequence in which the immediate contents of this division are to be processed, or their inter-relationships.

parallel the contents of this element are intended to represent simultaneous or side-by-side delivery.

uniform the immediate contents of this element are regarded as forming a logical unit, to be processed in sequence.[Default]

`@sample` indicates whether this division is a sample of the original source and if so, from which part.

Status Optional

Datatype teidata.enumerated

Legal values are: **initial** division lacks material present at end in source.

medial division lacks material at start and end.

final division lacks material at start.

unknown position of sampled material within original unknown.

complete division is not a sample.[Default]

---

att.docStatus provides attributes for use on metadata elements describing the status of a document.

Module tei — The TEI Infrastructure

Members bibl biblFull biblStruct change msDesc object post revisionDesc schemaSpec

Attributes

`@status` describes the status of a document either currently or, when associated with a dated element, at the time indicated.

Status Optional

Datatype teidata.enumerated

Sample values include: **approved**

```

```
    <change when="2010-03-01" status="draft"
      who="#LB"/>
  </revisionDesc>
```

---

att.duration provides attributes for normalization of elements that contain datable events.

Module spoken — Transcriptions of Speech

Members att.timed[annotationBlock binaryObject ellipsis gap incident kinesic media pause post u vocal writing] date recording time

Attributes

- att.duration.iso
  - *@dur-iso*
- att.duration.w3c
  - *@dur*

This 'superclass' provides attributes that can be used to provide normalized values of temporal information. By default, the attributes from the `att.duration.w3c` class are provided. If the module for names & dates is loaded, this class also provides attributes from the `att.duration.iso` class. In general, the possible values of attributes restricted to the W3C datatypes form a subset of those values available via the ISO 8601 standard. However, the greater expressiveness of the ISO datatypes is rarely needed, and there exists much greater software support for the W3C datatypes.

---

att.duration.iso provides attributes for recording normalized temporal durations. [*3.6.4. Dates and Times 14.4. Dates*]

Module tei — The TEI Infrastructure

Members att.duration[att.timed[annotationBlock binaryObject ellipsis gap incident kinesic media pause post u vocal writing] date recording time]

Attributes

`@dur-iso` (duration) indicates the length of this element in time.

Status Optional

Datatype teidata.duration.iso

If both *when* and *dur* or *dur-iso* are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. In order to represent a time range by a duration and its ending time the *when-iso* attribute must be used.

In providing a 'regularized' form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

---

att.duration.w3c provides attributes for recording normalized temporal durations. [*3.6.4. Dates and Times 14.4. Dates*]

Module tei — The TEI Infrastructure

Members att.duration[att.timed[annotationBlock binaryObject ellipsis gap incident kinesic media pause post u vocal writing] date recording time]

Attributes

`@dur` (duration) indicates the length of this element in time.

Status Optional

Datatype teidata.duration.w3c

If both *when* and *dur* are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. In order to represent a time range by a duration and its ending time the *when-iso* attribute must be used.

In providing a 'regularized' form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

---

att.edition

Oda provides attributes identifying the source edition from which some encoded feature derives.

Module tei — The TEI Infrastructure

Members cb gb lb milestone pb refState

Attributes

`@ed` (edition) supplies a sigil or other arbitrary identifier for the source edition in which the associated feature (for example, a page, column, or line beginning) occurs at this point in the text.
Status Optional
Datatype 1–∞ occurrences of teidata.word separated by whitespace

`@edRef` (edition reference) provides a pointer to the source edition in which the associated feature (for example, a page, column, or line beginning) occurs at this point in the text.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Example

```
<l>Of Mans First Disobedience,<lb ed="1674"/> and<lb ed="1667"/> the
Fruit</l>
<l>Of that Forbidden Tree, whose<lb ed="1667 1674"/> mortal tast</l>
<l>Brought Death into the World,<lb ed="1667"/> and all<lb ed="1674"/> our
woe,</l>
```

Example

```
<listBibl>
  <bibl xml:id="stapledon1937">
    <author>Olaf Stapledon</author>,
  <title>Starmaker</title>, <publisher>Methuen</publisher>, <date>1937</date>
  </bibl>
  <bibl xml:id="stapledon1968">
    <author>Olaf Stapledon</author>,
  <title>Starmaker</title>, <publisher>Dover</publisher>, <date>1968</date>
  </bibl>
</listBibl>
<!-- ... -->
<p>Looking into the future aeons from the supreme moment of
the cosmos, I saw the populations still with all their
strength maintaining the<pb n="411" edRef="#stapledon1968"/>essentials of
their ancient culture,
still living their personal lives in zest and endless
novelty of action, … I saw myself still
preserving, though with increasing difficulty, my lucid
con<pb n="291" break="no"
   edRef="#stapledon1937"/>sciousness;</p>
```

In the above example, the soft hyphen in Stapledon 1937 is omitted. Such decisions may be

documented in the edition's declaration of editorial principles, e.g. with the <hyphenation> element in the <teiHeader>.

Note These guidelines provide no semantic basis or suggested precedence when both *ed* and *edRef* are provided. For this reason simultaneous use of both is not recommended unless documentation explaining the use is provided, probably in an ODD customization, for interchange.

---

att.editLike provides attributes describing the nature of an encoded scholarly intervention or interpretation of any kind. [*3.5. Simple Editorial Changes 11.3.1. Origination 14.3.2. The Person Element 12.3.1.1. Core Elements for Transcriptional Work*]

Module tei — The TEI Infrastructure

Members att.transcriptional[add addSpan del delSpan mod redo restore retrace rt subst substJoin undo] affiliation age am birth climate corr date death education event eventName ex expan faith floruit gap gender geogFeat geogName langKnowledge langKnown location name nationality objectName occupation offset org orgName origDate origPlace origin persName persPronouns person persona place placeName population reg relation residence secl sex socecStatus state supplied surplus terrain time trait unclear

Attributes

`@evidence` indicates the nature of the evidence supporting the reliability or accuracy of the intervention or interpretation.
Status Optional
Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace
Suggested values include: **internal** there is internal evidence to support the intervention.
external there is external evidence to support the intervention.
conjecture the intervention or interpretation has been made by the editor, cataloguer, or scholar on the basis of their expertise.

`@instant` indicates whether this is an instant revision or not.
Status Optional
Datatype teidata.xTruthValue
Default false

The members of this attribute class are typically used to represent any kind of editorial intervention in a text, for example a correction or interpretation, or to date or localize manuscripts etc.

Each pointer on the *source* (if present) corresponding to a witness or witness group should reference a bibliographic citation such as a <witness>, <msDesc>, or <bibl> element, or another external bibliographic citation, documenting the source concerned.

---

att.enjamb (enjambement) provides attributes that may be used to indicate enjambement of the parent element. [*6.2. Components of the Verse Line*]

Module verse — Verse

Members l

Attributes

`@enjamb` (enjambement) indicates that the end of a verse line is marked by enjambement.
Status Optional
Datatype teidata.enumerated
Sample values include: **no** the line is end-stopped
yes the line in question runs on into the next
weak the line is weakly enjambed

strong the line is strongly enjambed

Note The usual practice will be to give the value 'yes' to this attribute when enjambement is being marked, or the values 'weak' and 'strong' if degrees of enjambement are of interest; if no value is given, however, the attribute does not default to a value of 'no'; this allows the attribute to be omitted entirely when enjambement is not of particular interest.

---

att.entryLike provides attributes used to distinguish different styles of dictionary entries. [*10.1. Dictionary Body and Overall Structure 10.2. The Structure of Dictionary Entries*]

Module dictionaries — Dictionaries

Members entry entryFree superEntry

Attributes

- att.typed
  - ~~type~~
  - @subtype

`@type` indicates type of entry, in dictionaries with multiple types.

Status Optional

Datatype teidata.enumerated

Suggested values include: **main** a main entry (default).[Default]

hom (homograph) groups information relating to one homograph within an entry.

xref (cross reference) a reduced entry whose only function is to point to another main entry (e.g. for forms of an irregular verb or for variant spellings: *was* pointing to *be*, or *esthete* to *aesthete*).

affix an entry for a prefix, infix, or suffix.

abbr (abbreviation) an entry for an abbreviation.

supplemental a supplemental entry (for use in dictionaries which issue supplements to their main work in which they include updated information about entries).

foreign an entry for a foreign word in a monolingual dictionary.

The global *n* attribute may be used to encode the homograph numbers attached to entries for homographs.

---

att.formula provides attributes for defining a mathematical formula. [*2.3.9. The Unit Declaration*]

Module tei — The TEI Infrastructure

Members conversion

Attributes

`@formula` A *formula* is provided to describe a mathematical calculation such as a conversion between measurement systems.

Status Optional

Datatype teidata.xpath

Example

```
<encodingDesc>
  <unitDecl>
    <unitDef  xml:id="stadium"  type="linear">
      <label>stadium</label>
      <placeName  ref="#rome"/>
      <conversion  fromUnit="#pes"
```

```
        toUnit="#stadium"  formula="$fromUnit * 625"/>
      <desc>The stadium was a Roman unit of linear measurement equivalent to 625
pedes, or Roman feet.</desc>
    </unitDef>
  </unitDecl>
</encodingDesc>
```

Example

```
<encodingDesc>
  <unitDecl>
    <unitDef  xml:id="wmw"  type="power">
      <label>whatmeworry</label>
      <conversion  fromUnit="#hpk"
        toUnit="#wmw"  formula="$fromUnit * 1"/>
      <desc>In the Potrzebie system of measures as introduced by Donald Knuth,
the whatmeworry unit of power is equivalent to one hah per kovac.</desc>
    </unitDef>
    <unitDef  xml:id="kwmw"  type="power">
      <label>kilowhatmeworry</label>
      <conversion  fromUnit="#wmw"
        toUnit="#kwmw"  formula="$fromUnit div 1000"/>
      <desc>The kilowhatmeworry is equivalent to 1000 whatmeworries.</desc>
    </unitDef>
    <unitDef  xml:id="ap"  type="power">
      <label>kilowhatmeworry</label>
      <conversion  fromUnit="#kwmw"
        toUnit="#ap"  formula="$fromUnit div 100"/>
      <desc>One unit of aeolipower (A.P.) is equivalent to 100
kilowhatmeworries.</desc>
    </unitDef>
  </unitDecl>
</encodingDesc>
```

Example

```
<conversion  fromUnit="#furlongsPerFortnight"
  toUnit="#milesPerHour"
  formula="$fromUnit cast as xs:decimal * 0.000372"/>
```

Example

```
<conversion  fromUnit="#deciday"
  toUnit="hour"
  formula="$fromUnit cast as xs:decimal * 144 div 60"/>
```

Note This attribute class provides *formula* for use in defining a value used in mathematical calculation. It can be used to store a mathematical operation needed to convert from one system of measurement to another. We use the teidata.xpath datatype to express this value in order to communicate mathematical operations on an XML node or nodes. The $fromUnit variable notation simplifies referencing of the *fromUnit* attribute on the parent <conversion> element. Note that 'div' is required to express the division operator in XPath.

---

att.fragmentable provides attributes for representing fragmentation of a structural element, typically as a consequence of some overlapping hierarchy.

Module tei — The TEI Infrastructure

Members att.divLike[div div1 div2 div3 div4 div5 div6 div7 lg spGrp] att.segLike[c cl m pc phr s seg w] ab l p post

Attributes

`@part` specifies whether or not its parent element is fragmented in some way, typically by some other overlapping structure: for example a speech which is divided between two or more verse stanzas, a paragraph which is split across a page division, a verse line which is divided between two speakers.

Status Optional

Datatype teidata.enumerated

Legal values are: **Y** (yes) the element is fragmented in some (unspecified) respect

N (no) the element is not fragmented, or no claim is made as to its completeness[Default]

I (initial) this is the initial part of a fragmented element

M (medial) this is a medial part of a fragmented element

F (final) this is the final part of a fragmented element

Note The values I, M, or F should be used only where it is clear how the element may be reconstituted.

---

att.gaijiProp provides attributes for defining the properties of non-standard characters or glyphs. [*5. Characters, Glyphs, and Writing Modes*]

12.1
13.0
14.0
15.0
unassigned

`@scheme` supplies the name of the character set system from which this property is drawn.
Status Optional
Datatype teidata.enumerated
Sample values include: **Unicode** (Unicode) ISO 10646[Default]
Bridwell (E. Nelson Bridwell) Original character set developed by E. Nelson Bridwell as described by Al Turniansky, in use from the 1950s to 1985.
Brewer (Georg Brewer) Developed by Georg Brewer, with a look similar to the Byrne glyphs. Like the Byrne set, this is not a true character set, but rather a set of alternate glyphs.

Doyle (Darren Doyle) Glyph set (in some cases associated with multiple characters) developed by Darren Doyle as part of a comprehensive version of the language created in part for an invented language classs at UT Austin in 2006.

Schreyer (Christine Schreyer) Character set (without actual codepoints) of 153 characters developed, along with pronunciation rules, roughly 300 words, and a grammar, developed by Christine Schreyer developed in 2012 for Warner Brothers.

Example In this example a definition for the Unicode property Decomposition Mapping is provided.

```
<unicodeProp name="Decomposition_Mapping"
  value="circle"/>
```

Note All name-only attributes need an xs:boolean attribute value inside *value*.

---

att.global provides attributes common to all elements in the TEI encoding scheme. [*1.3.1.1. Global Attributes*]

`@xml:id` (identifier) provides a unique identifier for the element bearing the attribute.

Status Optional

Datatype ID

Note The *xml:id* attribute may be used to specify a canonical reference for an element; see section *3.11. Reference Systems*.

`@n` (number) gives a number (or other label) for an element, which is not necessarily unique within the document.

Status Optional

Datatype teidata.text

Note The value of this attribute is always understood to be a single token, even if it contains space or other punctuation characters, and need not be composed of

numbers only. It is typically used to specify the numbering of chapters, sections, list items, etc.; it may also be used in the specification of a standard reference system for the text.

`@xml:lang` (language) indicates the language of the element content using a 'tag' generated according to BCP 47.

Status Optional

Datatype teidata.language

```
<p> … The consequences of
this rapid depopulation were the loss of the last
<foreign  xml:lang="rap">ariki</foreign> or chief
(Routledge 1920:205,210) and their connections to
ancestral territorial organization.</p>
```

Note The *xml:lang* value will be inherited from the immediately enclosing element, or from its parent, and so on up the document hierarchy. It is generally good practice to specify *xml:lang* at the highest appropriate level, noticing that a different default may be needed for the <teiHeader> from that needed for the associated resource element or elements, and that a single TEI document may contain texts in many languages.

Only attributes with free text values (rare in these guidelines) will be in the scope of *xml:lang*.

The authoritative list of registered language subtags is maintained by IANA and is available at https://www.iana.org/assignments/language-subtag-registry. For a good general overview of the construction of language tags, see https://www.w3.org/International/articles/language-tags/, and for a practical step-by-step guide, see https://www.w3.org/International/questions/qa-choosing-language-tags.en.php.

The value used must conform with BCP 47. If the value is a private use code (i.e., starts with x- or contains -x-), a <language> element with a matching value for its *ident* attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their (IETF) Internet Engineering Task Force definitions.

`@xml:base` provides a base URI reference with which applications can resolve relative URI references into absolute URI references.

Status Optional

Datatype teidata.pointer

```
<div  type="bibl">
  <head>Selections from <title  level="m">The Collected Letters
of Robert Southey. Part 1: 1791-1797</title>
  </head>
  <listBibl  xml:base="https://romantic-circles.org/sites/default/files/imported/editi
    <bibl>
      <ref  target="letterEEd.26.3.xml">
        <title>Robert Southey to Grosvenor Charles
Bedford</title>, <date  when="1792-04-03">3 April 1792</date>.
      </ref>
    </bibl>
    <bibl>
      <ref  target="letterEEd.26.57.xml">
        <title>Robert Southey to Anna Seward</title>,
<date  when="1793-09-18">18 September 1793</date>.
      </ref>
    </bibl>
```

```
      <bibl>
        <ref  target="letterEEd.26.85.xml">

    <date  from="1794-04-05"
           to="1794-04-06">5-6 April, 1794</date>.
        </ref>
      </bibl>
    </listBibl>
  </div>
```

`@xml:space` signals an intention about how white space should be managed by applications.

Status Optional

Datatype teidata.enumerated

Legal values are: **default** signals that the application's default white-space processing modes are acceptable

preserve indicates the intent that applications preserve all white space

Note The XML specification provides further guidance on the use of this attribute. Note that many parsers may not handle xml:space correctly.

---

att.global.analytic provides additional global attributes for associating specific analyses or interpretations with appropriate portions of a text. [*18.2. Global Attributes for Simple Analyses 18.3. Spans and Interpretations*]

Module analysis — Simple Analytic Mechanisms

Attributes

`@corresp` (corresponds) points to elements that correspond to the current element in some way.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

```
<group>
  <text  xml:id="t1-g1-t1"
    xml:lang="mi">
    <body  xml:id="t1-g1-t1-body1">
      <div  type="chapter">
        <head>He Whakamaramatanga mo te Ture Hoko, Riihi hoki, i
nga Whenua Maori, 1876.</head>
        <p>…</p>
      </div>
    </body>
```

```
  </text>
  <text  xml:id="t1-g1-t2"
    xml:lang="en">
    <body  xml:id="t1-g1-t2-body1"
      corresp="#t1-g1-t1-body1">
      <div  type="chapter">
        <head>An Act to regulate the Sale, Letting, and Disposal
of Native Lands, 1876.</head>
        <p>…</p>
      </div>
    </body>
  </text>
</group>In this example a <group> contains two <text>s, each
containing the same document in a different language. The
correspondence is indicated using corresp. The language is
indicated using xml:lang, whose value is inherited; both the tag
with the corresp and the tag pointed to by the corresp inherit
the value from their immediate parent.

<!-- In a placeography called "places.xml"
--><place  xml:id="LOND1"
  corresp="people.xml#LOND2 people.xml#GENI1">
  <placeName>London</placeName>
  <desc>The city of London...</desc>
</place>
<!-- In a literary personography called "people.xml" -->
<person  xml:id="LOND2"
  corresp="places.xml#LOND1 #GENI1">
  <persName  type="lit">London</persName>
  <note>
    <p>Allegorical character representing the city of
<placeName  ref="places.xml#LOND1">London</placeName>.</p>
  </note>
</person>
<person  xml:id="GENI1"
  corresp="places.xml#LOND1 #LOND2">
  <persName  type="lit">London's Genius</persName>
  <note>
    <p>Personification of London's genius. Appears as an
        allegorical character in mayoral shows.
    </p>
  </note>
</person>In this example, a <place> element containing
information about the city of London is linked with two <person>
elements in a literary personography. This correspondence
represents a slightly looser relationship than the one in the
preceding example; there is no sense in which an allegorical
character could be substituted for the physical city, or vice
versa, but there is obviously a correspondence between them.
```

`@synch` (synchronous) points to elements that are synchronous with the current element.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@sameAs` points to an element that is the same as the current element.

Status Optional

Datatype teidata.pointer

`@copyOf` points to an element of which the current element is a copy.

Status Optional

Datatype teidata.pointer

Note Any content of the current element should be ignored. Its true content is that of the element being pointed at.

`@next` (next) points to the next element of a virtual aggregate of which the current element is part.

Status Optional

Datatype teidata.pointer

Note It is recommended that the element indicated be of the same type as the element bearing this attribute.

`@prev` (previous) points to the previous element of a virtual aggregate of which the current element is part.

Status Optional

Datatype teidata.pointer

Note It is recommended that the element indicated be of the same type as the element bearing this attribute.

`@exclude` points to elements that are in exclusive alternation with the current element.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@select` selects one or more alternants; if one alternant is selected, the ambiguity or uncertainty is marked as resolved. If more than one alternant is selected, the degree of ambiguity or uncertainty is marked as reduced by the number of alternants not selected.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note This attribute should be placed on an element which is superordinate to all of the alternants from which the selection is being made.

---

att.global.rendition provides rendering attributes common to all elements in the TEI encoding scheme. [*1.3.1.1.3. Rendition Indicators*]

Module tei — The TEI Infrastructure

Members att.global[TEI ab abbr abstract accMat acquisition activity actor add addName addSpan additional additions addrLine address adminInfo affiliation age alt altGrp altIdent altIdentifier alternate am analytic anchor annotation annotationBlock anyElement app appInfo application arc argument att attDef attList attRef author authority availability back bibl biblFull biblScope biblStruct bicond binary binaryObject binding bindingDesc birth bloc body broadcast byline c cRefPattern caesura calendar calendarDesc camera caption case castGroup castItem castList catDesc catRef catchwords category cb cell certainty change channel char charDecl choice cit citeData citeStructure citedRange cl classCode classDecl classRef classSpec classes climate closer code collation collection colloc colophon cond condition constitution constraint constraintDecl constraintSpec content conversion corr correction correspAction correspContext correspDesc country creation custEvent custodialHist damage damageSpan dataFacet dataRef dataSpec datatype date dateline death decoDesc decoNote def default defaultVal del delSpan depth derivation desc dictScrap dim dimensions distinct distributor district div div1 div2 div3 div4 div5 div6 div7 divGen docAuthor docDate docEdition docImprint docTitle domain eLeaf eTree edition editionStmt editor editorialDecl education eg egXML elementRef elementSpec ellipsis email emph empty encodingDesc entry entryFree epigraph epilogue equipment equiv etym event eventName ex exemplum expan explicit extent f fDecl fDescr fLib facsimile factuality faith figDesc figure fileDesc filiation finalRubric floatingText floruit foliation foreign forename forest form formula front fs fsConstraints fsDecl fsDescr fsdDecl fsdLink funder fvLib fw g gap gb gen genName gender geo geoDecl geogFeat geogName gi gloss glyph gram gramGrp graph graphic group handDesc handNote handNotes handShift head headItem headLabel height heraldry hi history hom hyph hyphenation iNode iType ident idno if iff imprimatur imprint incident incipit index institution interaction interleave interp interpGrp

Attributes

`@rend` (rendition) indicates how the element in question was rendered or presented in the source text.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

```
<head  rend="align(center) case(allcaps)">
  <lb/>To The <lb/>Duchesse <lb/>of <lb/>Newcastle,
<lb/>On Her <lb/>
  <hi  rend="case(mixed)">New Blazing-World</hi>.
</head>
```

Note These Guidelines make no binding recommendations for the values of the *rend* attribute; the characteristics of visual presentation vary too much from text to text and the decision to record or ignore individual characteristics varies too much from project to project. Some potentially useful conventions are noted from time to time at appropriate points in the Guidelines. The values of the *rend* attribute are a set of sequence-indeterminate individual tokens separated by whitespace.

`@style` contains an expression in some formal style definition language which defines the rendering or presentation used for this element in the source text.

Status Optional

Datatype teidata.text

```
<head  style="text-align: center; font-variant: small-caps;">
  <lb/>To The <lb/>Duchesse <lb/>of <lb/>Newcastle, <lb/>On Her
<lb/>
```

```
  <hi  style="font-variant: normal">New Blazing-World</hi>.
</head>
```

Note Unlike the attribute values of *rend*, which uses whitespace as a separator, the *style* attribute may contain whitespace. This attribute is intended for recording inline stylistic information concerning the source, not any particular output.

The formal language in which values for this attribute are expressed may be specified using the <styleDefDecl> element in the TEI header.

If *style* and *rendition* are both present on an element, then *style* overrides or complements *rendition*. *style* should not be used in conjunction with *rend*, because the latter does not employ a formal style definition language.

`@rendition` (rendition reference) points to a description of the rendering or presentation used for this element in the source text.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

```
<head  rendition="#ac #sc">
  <lb/>To The <lb/>Duchesse <lb/>of <lb/>Newcastle, <lb/>On Her
<lb/>
  <hi  rendition="#normal">New Blazing-World</hi>.
</head>
<!-- elsewhere... -->
<rendition  xml:id="sc"
  scheme="css">font-variant: small-caps</rendition>
<rendition  xml:id="normal"
  scheme="css">font-variant: normal</rendition>
<rendition  xml:id="ac"
  scheme="css">text-align: center</rendition>
```

Note The *rendition* attribute is used in a very similar way to the *class* attribute defined for XHTML but with the important distinction that its function is to describe the appearance of the source text, not necessarily to determine how that text should be presented on screen or paper.

If *rendition* is used to refer to a style definition in a formal language like CSS, it is recommended that it not be used in conjunction with *rend*.

Each URI provided should indicate a <rendition> element defining the intended rendition in terms of some appropriate style language, as indicated by the *scheme* attribute.

These guidelines provide no semantic basis or suggested precedence when both *rend* and *rendition* are provided. For this reason simultaneous use of both is not recommended for interchange unless documentation explaining the use is provided, probably in an ODD customization.

---

att.global.responsibility

att.global.responsibility provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it. [*1.3.1.1.4. Sources, certainty, and responsibility 3.5. Simple Editorial Changes 12.3.2.2. Hand, Responsibility, and Certainty Attributes 18.3. Spans and Interpretations 14.1.1. Attributes

`@cert` (certainty) signifies the degree of certainty associated with the intervention or interpretation.
Status Optional
Datatype teidata.probCert

`@resp` (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note To reduce the ambiguity of a *resp* pointing directly to a person or organization, we recommend that *resp* be used to point not to an agent (<person> or <org>) but to a <respStmt>, <author>, <editor> or similar element which clarifies the exact role played by the agent. Pointing to multiple <respStmt>s allows the encoder to specify clearly each of the roles played in part of a TEI file (creating, transcribing, encoding, editing, proofing etc.).

Example

```
Blessed are the
<choice>
  <sic>cheesemakers</sic>
  <corr  resp="#editor"  cert="high">peacemakers</corr>
</choice>: for they shall be called the children of God.
```

Example

```
<!-- in the <text> ... --><lg>
<!-- ... -->
  <l>Punkes, Panders, baſe extortionizing
     sla<choice>
      <sic>n</sic>
      <corr  resp="#JENS1_transcriber">u</corr>
    </choice>es,</l>
<!-- ... -->
</lg>
<!-- in the <teiHeader> ... -->
<!-- ... -->
<respStmt  xml:id="JENS1_transcriber">
  <resp  when="2014">Transcriber</resp>
  <name>Janelle Jenstad</name>
</respStmt>
```

---

att.global.source provides attributes used by elements to point to an external source. [*1.3.1.1.4. Sources, certainty, and responsibility 3.3.3. Quotation 8.3.4. Writing*]

Module tei — The TEI Infrastructure

Members att.global[TEI ab abbr abstract accMat acquisition activity actor add addName addSpan additional additions addrLine address adminInfo affiliation age alt altGrp altIdent altIdentifier alternate am analytic anchor annotation annotationBlock anyElement app appInfo application arc argument att attDef attList attRef author authority availability back bibl biblFull biblScope biblStruct bicond binary binaryObject binding bindingDesc birth bloc body broadcast byline c cRefPattern caesura calendar calendarDesc camera caption case castGroup castItem castList catDesc catRef catchwords category cb cell certainty change channel char charDecl choice cit citeData citeStructure citedRange cl classCode classDecl classRef classSpec classes climate closer code collation collection colloc colophon cond condition constitution constraint constraintDecl constraintSpec content conversion corr correction correspAction correspContext correspDesc country creation custEvent custodialHist damage damageSpan dataFacet dataRef dataSpec datatype date dateline death decoDesc decoNote def default defaultVal del delSpan depth derivation desc dictScrap dim dimensions distinct distributor district div div1 div2 div3 div4 div5 div6 div7 divGen docAuthor docDate docEdition docImprint docTitle domain eLeaf eTree edition editionStmt editor editorialDecl education eg egXML elementRef elementSpec ellipsis email emph empty encodingDesc entry entryFree epigraph epilogue equipment equiv etym event eventName ex exemplum expan explicit extent f fDecl fDescr fLib facsimile factuality faith figDesc figure fileDesc filiation finalRubric floatingText floruit foliation foreign forename forest form formula front fs fsConstraints

Attributes

`@source` specifies the source from which some aspect of this element is drawn.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Schematron <sch:rule context="tei:*[@source]"> <sch:let name="srcs" value="tokenize(normalize-space(@source),' ')"/> <sch:report test="(self::tei:classRef | self::tei:dataRef | self::tei:elementRef | self::tei:macroRef | self::tei:moduleRef | self::tei:schemaSpec) and $srcs[2]"> When used on a schema description element (like «sch:value-of select="name(.)"/»), the @source attribute should have only 1 value. (This one has <sch:value-of select="count($srcs)"/>.) </sch:report> </sch:rule>

Note The *source* attribute points to an external source. When used on an element describing a schema component (<classRef>, <dataRef>, <elementRef>, <macroRef>, <moduleRef>, or <schemaSpec>), it identifies the source from which declarations for the components should be obtained.

On other elements it provides a pointer to the bibliographical source from which a quotation or citation is drawn.

In either case, the location may be provided using any form of URI, for example an absolute URI, a relative URI, a private scheme URI of the form `tei:x.y.z`, where `x.y.z` indicates the version number, e.g. `tei:4.3.2` for TEI P5 release 4.3.2 or (as a special case) `tei:current` for whatever is the latest release, or a private scheme URI that is expanded to an absolute URI as documented in a <prefixDef>.

When used on elements describing schema components, *source* should have only one value; when used on other elements multiple values are permitted.

Example

```
<p>
<!-- ... --> As Willard McCarty (<bibl  xml:id="mcc_2012">2012, p.2</bibl>)
tells us, <quote  source="#mcc_2012">‘Collaboration’ is a problematic and
should be a contested
    term.</quote>
<!-- ... -->
</p>
```

Example

```
<p>
<!-- ... -->
  <quote  source="#chicago_15_ed">Grammatical theories are in flux, and the
more we learn, the
    less we seem to know.</quote>
<!-- ... -->
</p>
<!-- ... -->
<bibl  xml:id="chicago_15_ed">
  <title  level="m">The Chicago Manual of Style</title>,
<edition>15th edition</edition>. <pubPlace>Chicago</pubPlace>:
<publisher>University of
    Chicago Press</publisher> (<date>2003</date>),
<biblScope  unit="page">p.147</biblScope>.

</bibl>
```

Example

```
<elementRef  key="p"  source="tei:2.0.1"/>
```

Include in the schema an element named <p> available from the TEI P5 2.0.1 release.

Example

```
<schemaSpec  ident="myODD"
  source="mycompiledODD.xml">
<!-- further declarations specifying the components required -->
</schemaSpec>
```

Create a schema using components taken from the file `mycompiledODD.xml`.

---

att.handFeatures provides attributes describing aspects of the hand in which a manuscript is written. [*12.3.2.1. Document Hands*]

Module tei — The TEI Infrastructure

Members handNote handShift scriptNote typeNote

Attributes
- att.scope
  - *@scope*

`@scribe` gives a name or other identifier for the scribe believed to be responsible for this hand.

Status Optional

Datatype teidata.name

`@scribeRef` points to a full description of the scribe concerned, typically supplied by a <person> element elsewhere in the description.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@script` characterizes the particular script or writing style used by this hand, for example *secretary*, *copperplate*, *Chancery*, *Italian*, etc.
Status Optional
Datatype 1–∞ occurrences of teidata.name separated by whitespace

`@scriptRef` points to a full description of the script or writing style used by this hand, typically supplied by a <scriptNote> element elsewhere in the description.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@medium` describes the tint or type of ink, e.g. *brown*, or other writing medium, e.g. *pencil*.
Status Optional
Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace

These guidelines provide no semantic basis or suggested precedence when both *script* and *scriptRef* or when both *scribe* and *scribeRef* are provided. For this reason simultaneous use of either pair of attributes is not recommended for interchange unless documentation explaining the use is provided, probably in an ODD customization.

---

att.identified

Module provides identifying attributes for elements which can be subsequently referenced by means of a *key* attribute.

Module tagdocs — Documentation Elements

Members attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec

Attributes
- att.combinable
  - *@mode*
- att.deprecated
  - *@validUntil*

`@ident` supplies the identifier by which this element may be referenced.
Status Required
Datatype teidata.name

`@predeclare` says whether this object should be predeclared in the `tei` infrastructure module.
Status Optional
Datatype teidata.truthValue
Default false

`@module` supplies a name for the module in which this object is to be declared.
Status Optional
Datatype teidata.xmlName

Schematron <sch:rule context="(tei:elementSpec[@module] | tei:classSpec[@module] | tei:macroSpec[@module])[(ancestor::tei:schemaSpec | ancestor::tei:TEI | ancestor::tei:teiCorpus) and (//tei:moduleSpec | //tei:moduleRef)]"> <sch:assert test="(//tei:moduleSpec/@ident | //tei:moduleRef/@key) = @module"> Specification <sch:value-of select="@ident"/>: the value of the module attribute ("<sch:value-of select="@module"/>") should correspond to an existing module, via a moduleSpec or moduleRef.</sch:assert> </sch:rule>

---

att.indentation provides attributes for describing the indentation of a textual element on the source page or object. [*9.3.2. Attributes Specific to CMC post*]

Module tei — The TEI Infrastructure

Members post

Attributes

`@indentLevel` specifies the level of indentation of an item using a numeric value.

Status Recommended

Datatype integer

Note This attribute can be used to mark the level of indentation of a post in a thread-like structure (as defined by its author and in relation to the standard level of indentation which should be encoded with 0). This is commonly used for Wiki talk pages, but should also be used for genres such as webblog comments when the source was HTML.

---

att.internetMedia provides attributes for specifying the type of a computer resource using a standard taxonomy.

Module tei — The TEI Infrastructure

Members att.media[binaryObject graphic media] equiv ptr ref

Attributes

`@mimeType` (MIME media type) specifies the applicable multimedia internet mail extension (MIME) media type.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

Example In this example *mimeType* is used to indicate that the URL points to a TEI XML file encoded in UTF-8.

```
<ref  mimeType="application/tei+xml; charset=UTF-8"
  target="https://raw.githubusercontent.com/TEIC/TEI/dev/P5/Source/guidelines-en.xml"/>
```

Note This attribute class provides an attribute for describing a computer resource, typically available over the internet, using a value taken from a standard taxonomy. At present only a single taxonomy is supported, the Multipurpose Internet Mail Extensions (MIME) Media Type system. This typology of media types is defined by the Internet Engineering Task Force in RFC 2046. The list of types is maintained by the Internet Assigned Numbers Authority (IANA). The *mimeType* attribute must have a value taken from this list.

---

att.interpLike provides attributes for elements which represent a formal analysis or interpretation. [*18.2. Global Attributes for Simple Analyses*]

Module tei — The TEI Infrastructure

Members interp interpGrp span spanGrp

Attributes

`@type` indicates what kind of phenomenon is being noted in the passage.

Status Recommended

Datatype teidata.enumerated

Sample values include: **image** identifies an image in the passage.

character identifies a character associated with the passage.

theme identifies a theme in the passage.

allusion identifies an allusion to another text.

`@subtype` (subtype) provides a sub-categorization of the phenomenon is being noted in the passage, if needed.
Status Optional
Datatype teidata.enumerated
Note The *subtype* attribute may be used to provide any sub-classification for the element additional to that provided by its *type* attribute.

`@inst` (instances) points to instances of the analysis or interpretation represented by the current element.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace
Note The current element should be an analytic one. The element pointed at should be a textual one.

---

att.lexicographic provides a set of attributes for specifying standard and normalized values, grammatical functions, alternate or equivalent forms, and information about composite parts. [*10.2. The Structure of Dictionary Entries*]

Module dictionaries — Dictionaries

Members case colloc def entryFree etym form gen gram gramGrp hom hyph iType lang lbl mood number oRef orth pRef per pos pron sense subc syll tns usg xr

Attributes
- att.datcat
  - *@datcat*
  - *@valueDatcat*
  - *@targetDatcat*
- att.lexicographic.normalized
  - *@norm*
  - *@orig*

`@expand` (expand) gives an expanded form of information presented more concisely in the dictionary.
Status Optional
Datatype teidata.text

```
<gramGrp>
  <pos  expand="noun">n</pos>
</gramGrp>
```

`@split` (split) gives the list of split values for a merged form.
Status Optional
Datatype teidata.text

`@value` (value) gives a value which lacks any realization in the printed source text.
Status Optional
Datatype teidata.text

`@location` (location) indicates an <anchor> element typically elsewhere in the document, but possibly in another document, which is the original location of this component.
Status Optional
Datatype teidata.pointer

`@mergedIn` (merged into) gives a reference to another element, where the original appears as a merged form.
Status Optional
Datatype teidata.pointer

`@opt` (optional) indicates whether the element is optional or not.

Status Optional
Datatype teidata.truthValue
Default false

---

att.lexicographic.normalized provides attributes for usage within word-level elements in the analysis module and within lexicographic microstructure in the dictionaries module.

Module analysis — Simple Analytic Mechanisms

Members att.lexicographic[case colloc def entryFree etym form gen gram gramGrp hom hyph iType lang lbl mood number oRef orth pRef per pos pron sense subc syll tns usg xr] att.linguistic[pc w]

Attributes

`@norm` (normalized) provides the normalized/standardized form of information present in the source text in a non-normalized form.

Status Optional

Datatype teidata.text

Normalization of part-of-speech information within a dictionary entry.
```
<gramGrp>
  <pos norm="noun">n</pos>
</gramGrp>
```
```
Normalization of a source form in a tokenized historical corpus.
<s>
  <w>for</w>
  <w norm="virtue's">vertues</w>
  <w>sake</w>
</s>
<s>
  <w norm="persuasion">perswasion</w>
  <w>of</w>
  <w norm="Unity">Vnitie</w>
</s>
Example of normalization from Aviso. Relation oder Zeitung.
Wolfenbüttel, 1609. In: Deutsches Textarchiv. <s>
  <w norm="freiwillig">freywillig</w>
  <pc norm=","
    join="left">/</pc>
  <w norm="unbedrängt">vnbedra□ngt</w>
  <w norm="und">vnd</w>
  <w norm="unverhindert">vnuerhindert</w>
</s>
<w norm="Teil">Theyll</w>
<w norm="Freude">Frewde</w>
```

`@orig` (original) gives the original string or is the empty string when the element does not appear in the source text.

Status Optional

Datatype teidata.text

Example from a language documentation project of the Mixtepec-Mixtec language (ISO 639-3: 'mix'). This is a use case where speakers spell something incorrectly but we would like to preserve it for any number of reasons, the use of *orig* is essential and could have uses for both the speaker to see past mistakes, researchers to get insight into how untrained speakers write their language instinctually (in contrast to prescribed convention), etc.: `<w orig="ntsa sia'i">ntsasia'i</w>`

```
Example from the EarlyPrint project. Fragment of text where
obvious errors have been corrected but the original forms remain
recorded: <w lemma="he"
```

```
  pos="pns"
  xml:id="b1afj-003-a-0950">he</w>
<w  lemma="have"
  pos="vvz"
  xml:id="b1afj-003-a-0960">hath</w>
<w  lemma="bring"
  pos="vvn"
  xml:id="b1afj-003-a-0970">brought</w>
<w  lemma="forth"
  pos="av"
  xml:id="b1afj-003-a-0980"
  orig="sorth">forth</w>
An example from the EarlyPrint project showing the use of both
norm and orig. The orig attribute preserves the original version
(sometimes with spelling errors, often with printer
abbreviations), the element content resolves printer
abbreviations but retains the original orthography, and the norm
attribute holds normalized values: <w  lemma="commandment"
  pos="n1"
  norm="commandment"
  xml:id="b9avr-018-a-7720"
  orig="commandemēt">commandement</w>
```

It needs to be stressed that the two attributes in this class are meant for strictly lexicographic and linguistic uses, and not for editorial interventions. For the latter, the mechanism based on <choice>, <orig>, and <reg> needs to be employed.

---

att.linguistic

att.linguistic provides a set of attributes concerning linguistic features of tokens, for usage within token-level elements, specifically <w> and <pc> in the analysis module. [*18.4.2. Lightweight Linguistic Annotation*]

Module analysis — Simple Analytic Mechanisms

Members pc w

Attributes • att.lexicographic.normalized

- *@norm*
- *@orig*

`@lemma` provides a lemma (base form) for the word, typically uninflected and serving both as an identifier (e.g. in dictionary contexts, as a headword), and as a basis for potential inflections.
Status Optional
Datatype teidata.text

```
<w  lemma="wife">wives</w>
<w  lemma="Arznei">Artzeneyen</w>
```

`@lemmaRef` provides a pointer to a definition of the lemma for the word, for example in an online lexicon.
Status Optional
Datatype teidata.pointer

```
<w  type="verb"
  lemma="hit"
  lemmaRef="http://www.example.com/lexicon/hitvb.xml">hitt<m  type="suffix">ing</m>
</w>
```

`@pos` (part of speech) indicates the part of speech assigned to a token (i.e. information on whether it is a noun, adjective, or verb), usually according to some official reference vocabulary (e.g. for German: STTS, for English: CLAWS, for Polish: NKJP, etc.).
Status Optional

Datatype teidata.text

The German sentence 'Wir fahren in den Urlaub.' tagged with the Stuttgart-Tuebingen-Tagset (STTS). **<s>**

```
<w pos="PPER">Wir</w>
<w pos="VVFIN">fahren</w>
<w pos="APPR">in</w>
<w pos="ART">den</w>
<w pos="NN">Urlaub</w>
<w pos="$.">.</w>
</s>
```

```
The English sentence 'We're going to Brazil.' tagged with the
CLAWS-5 tagset, arranged inline (with significant whitespace).
<p><w pos="PNP">We</w><w pos="VBB">'re</w> <w pos="VVG">going</w> <w pos="PRP">to<

The English sentence 'We're going on vacation to Brazil for a
month!' tagged with the CLAWS-7 tagset and arranged
sequentially. <p>
```

```
<w pos="PPIS2">We</w>
<w pos="VBR">'re</w>
<w pos="VVG">going</w>
<w pos="II">on</w>
<w pos="NN1">vacation</w>
<w pos="II">to</w>
<w pos="NP1">Brazil</w>
<w pos="IF">for</w>
<w pos="AT1">a</w>
<w pos="NNT1">month</w>
<pc pos="!">!</pc>
</p>
```

`@msd` (morphosyntactic description) supplies morphosyntactic information for a token, usually according to some official reference vocabulary (e.g. for German: STTS-large tagset; for a feature description system designed as (pragmatically) universal, see Universal Features).

Status Optional

Datatype teidata.text

```
<ab>
  <w pos="PPER"
    msd="1.Pl.*.Nom">Wir</w>
  <w pos="VVFIN"
    msd="1.Pl.Pres.Ind">fahren</w>
  <w pos="APPR"
    msd="--">in</w>
  <w pos="ART"
    msd="Def.Masc.Akk.Sg">den</w>
  <w pos="NN"
    msd="Masc.Akk.Sg">Urlaub</w>
  <pc pos="$."
    msd="--">.</pc>
</ab>
```

`@join` when present, provides information on whether the token in question is adjacent to another, and if so, on which side.

Status Optional

Datatype teidata.text

Legal values are: **no** the token is not adjacent to another

left there is no whitespace on the left side of the token

right there is no whitespace on the right side of the token

both there is no whitespace on either side of the token

overlap the token overlaps with another; other devices (specifying the extent and the area of overlap) are needed to more precisely locate this token in the character stream

The example below assumes that the lack of whitespace is marked redundantly, by using the appropriate values of *join*.

```
<s>
  <pc  join="right">"</pc>
  <w  join="left">Friends</w>
  <w>will</w>
  <w>be</w>
  <w  join="right">friends</w>
  <pc  join="both">.</pc>
  <pc  join="left">"</pc>
</s>Note that a project may make a decision to only indicate
lack of whitespace in one direction, or do that non-redundantly.
The existing proposal is the broadest possible, on the
assumption that we adopt the "streamable view", where all the
information on the current element needs to be represented
locally.
The English sentence ‘We're going on vacation.’ tagged with the
CLAWS-5 tagset, arranged sequentially, tagged on the assumption
that only the lack of the preceding whitespace is indicated. <p>
  <w  pos="PNP">We</w>
  <w  pos="VBB"
    join="left">'re</w>
  <w  pos="VVG">going</w>
  <w  pos="PRP">on</w>
  <w  pos="NN1">vacation</w>
  <pc  pos="PUN"
    join="left">.</pc>
</p>
```

Note The definition of this attribute is adapted from ISO MAF (Morpho-syntactic Annotation Framework), ISO 24611:2012.

These attributes make it possible to encode simple language corpora and to add a layer of linguistic information to any tokenized resource. See section *18.4.2. Lightweight Linguistic Annotation* for discussion.

These guidelines provide no semantic basis or suggested precedence when both *lemma* and *lemmaRef* are provided. For this reason simultaneous use of both is not recommended for interchange unless documentation explaining the use is provided, probably in an ODD customization.

---

att.locatable provides attributes for referencing locations by pointing to entries in a canonical list of places.

[*2.3.9. The Unit Declaration 14.3.4.3. States, Traits, and Events*]

Module tei — The TEI Infrastructure

Members birth conversion death event

Attributes

`@where` indicates one or more locations by pointing to a <place> element or other canonical description.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

---

att.measurement provides attributes to represent a regularized or normalized measurement.

Module tei — The TEI Infrastructure
Members measure measureGrp unit
Attributes

`@unit` (unit) indicates the units used for the measurement, usually using the standard symbol for the desired units.
Status Optional
Datatype teidata.enumerated
Suggested values include: **m** (metre) SI base unit of length
kg (kilogram) SI base unit of mass
s (second) SI base unit of time
Hz (hertz) SI unit of frequency
Pa (pascal) SI unit of pressure or stress
Ω (ohm) SI unit of electric resistance
L (litre) 1 dm^3
t (tonne) 10^3 kg
ha (hectare) 1 hm^2
Å (ångström) 10^{-10} m
mL (millilitre)
cm (centimetre)
dB (decibel) see remarks, below
kbit (kilobit) 10^3 or 1000 bits
Kibit (kibibit) 2^{10} or 1024 bits
kB (kilobyte) 10^3 or 1000 bytes
KiB (kibibyte) 2^{10} or 1024 bytes
MB (megabyte) 10^6 or 1 000 000 bytes
MiB (mebibyte) 2^{20} or 1 048 576 bytes
Note If the measurement being represented is not expressed in a particular unit, but rather is a number of discrete items, the unit count should be used, or the *unit* attribute may be left unspecified.
Wherever appropriate, a recognized SI unit name should be used (see further `http://www.bipm.org/en/publications/si-brochure/`; `http://physics.nist.gov/cuu/Units/`). The list above is indicative rather than exhaustive.

`@unitRef` points to a unique identifier stored in the *xml:id* of a <unitDef> element that defines a unit of measure.
Status Optional
Datatype teidata.pointer

`@quantity` (quantity) specifies the number of the specified units that comprise the measurement
Status Optional
Datatype teidata.numeric

`@commodity` (commodity) indicates the substance that is being measured
Status Optional
Datatype 1–∞ occurrences of teidata.word separated by whitespace
Note In general, when the commodity is made of discrete entities, the plural form should be used, even when the measurement is of only one of them.

This attribute class provides a triplet of attributes that may be used either to regularize the values of the measurement being encoded, or to normalize them with respect to a standard measurement system.

```
<l>
<!-- regularization:-->
So weren't you gonna buy <measure  quantity="0.5"  unit="gal"
   commodity="ice cream">half
    a gallon</measure>, baby
</l>
<l>
<!-- normalization: -->
So won't you go and buy <measure  quantity="1.893"  unit="L"
   commodity="ice cream">half
    a gallon</measure>, baby?
</l>
```

These guidelines provide no semantic basis or suggested precedence when both *unit* and *unitRef* are provided. For this reason simultaneous use of both is not recommended for interchange unless documentation explaining the use is provided, probably in an ODD customization.

In either case, the unit should normally be named using the standard symbol for an SI unit (see further `http://www.bipm.org/en/publications/si-brochure/`; `http://physics.nist.gov/cuu/Units/`). However, encoders may also specify measurements using informally defined units such as lines or characters.

---

att.media provides attributes for specifying display and related properties of external media.

Module tei — The TEI Infrastructure

Members binaryObject graphic media

Attributes • att.internetMedia
- *@mimeType*

`@width` Where the media are displayed, indicates the display width.
Status Optional
Datatype teidata.outputMeasurement

`@height` Where the media are displayed, indicates the display height.
Status Optional
Datatype teidata.outputMeasurement

`@scale` Where the media are displayed, indicates a scale factor to be applied when generating the desired display size.
Status Optional
Datatype teidata.numeric

---

att.metrical defines a set of attributes that certain elements may use to represent metrical information. [*6.4. Rhyme and Metrical Analysis*]

Module verse — Verse

Members att.divLike[div div1 div2 div3 div4 div5 div6 div7 lg spGrp] att.segLike[c cl m pc phr s seg w] l

Attributes

`@met` (metrical structure, conventional) contains a user-specified encoding for the conventional metrical structure of the element.
Status Recommended
Datatype token
Note The pattern may be specified by means of either a standard term for the kind of

metrical unit (e.g. *hexameter*) or an encoded representation for the metrical pattern (e.g. *+−+-+-+-+-*). In either case, the notation used should be documented by a <metDecl> element within the <encodingDesc> of the associated header.

Where this attribute is not specified, the metrical pattern for the element concerned is understood to be inherited from its parent.

`@real` (metrical structure, realized) contains a user-specified encoding for the actual realization of the conventional metrical structure applicable to the element.

Status Optional

Datatype token

Note The pattern may be specified by means of either a standard term for the kind of metrical unit (e.g. *hexameter*) or an encoded representation for the metrical pattern (e.g. *+−+-+-+-+-*). In either case, the notation used should be documented by a <metDecl> element within the <encodingDesc> of the associated header.

Where this attribute is not specified, the metrical realization for the element concerned is understood to be identical to that specified or implied for the *met* attribute.

`@rhyme` (rhyme scheme) specifies the rhyme scheme applicable to a group of verse lines.

Status Recommended

Datatype token

Note By default, the rhyme scheme is expressed as a string of alphabetic characters each corresponding with a rhyming line. Any non-rhyming lines should be represented by a hyphen or an X. Alternative notations may be defined as for *met* by use of the <metDecl> element in the TEI header.

When the default notation is used, it does not make sense to specify this attribute on any unit smaller than a line. Nor does the default notation provide any way to record internal rhyme, or to specify non-conventional rhyming practice. These extensions would require user-defined alternative notations.

---

att.milestoneUnit provides attributes to indicate the type of section which is changing at a specific milestone. [*3.11.3. Milestone Elements 2.3.6.3. Milestone Method 2.3.6. The Reference System Declaration*]

Module core — Elements Available in All TEI Documents

Members milestone refState

Attributes

`@unit` provides a conventional name for the kind of section changing at this milestone.

Status Required

Datatype teidata.enumerated

Suggested values include: **page** physical page beginnings (synonymous with the <pb> element).

column column beginnings.

line line beginnings (synonymous with the <lb> element).

book any units termed book, liber, etc.

poem individual poems in a collection.

canto cantos or other major sections of a poem.

speaker changes of speaker or narrator.

stanza stanzas within a poem, book, or canto.

act acts within a play.

scene scenes within a play or act.

section sections of any kind.

absent passages not present in the reference edition.

unnumbered passages present in the text, but not to be included as part of the reference.

```
<milestone n="23"
  ed="La"
  unit="Dreissiger"/>
... <milestone n="24"
  ed="AV"
  unit="verse"/> ...
```

Note If the milestone marks the beginning of a piece of text not present in the reference edition, the special value *absent* may be used as the value of *unit*. The normal interpretation is that the reference edition does not contain the text which follows, until the next <milestone> tag for the edition in question is encountered.

In addition to the values suggested, other terms may be appropriate (e.g. *Stephanus* for the Stephanus numbers in Plato).

The *type* attribute may be used to characterize the unit boundary in any respect other than simply identifying the type of unit, for example as word-breaking or not.

---

att.msClass provides attributes to indicate text type or classification. [*11.6. Intellectual Content 11.6.1. The msItem and msItemStruct Elements*]

Module msdescription — Manuscript Description

Members msContents msItem msItemStruct

Attributes

`@class` identifies the text types or classifications applicable to this item by pointing to other elements or resources defining the classification concerned.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

---

att.msExcerpt (manuscript excerpt) provides attributes used to describe excerpts from a manuscript placed in a description thereof. [*11.6. Intellectual Content*]

Module msdescription — Manuscript Description

Members colophon explicit finalRubric incipit msContents msItem msItemStruct quote rubric

Attributes

`@defective` indicates whether the passage being quoted is defective, i.e. incomplete through loss or damage.
Status Optional
Datatype teidata.xTruthValue

In the case of an incipit, indicates whether the incipit as given is defective, i.e. the first words of the text as preserved, as opposed to the first words of the work itself. In the case of an explicit, indicates whether the explicit as given is defective, i.e. the final words of the text as preserved, as opposed to what the closing words would have been had the text of the work been whole.

---

att.namespaceable provides attributes indicating the target namespace for an object being created.

Module tagdocs — Documentation Elements

Members attDef elementSpec schemaSpec

Attributes

`@ns` (namespace) specifies the namespace to which the element(s) being specified belongs.
Status Optional
Datatype 0–1 occurrences of teidata.namespace separated by whitespace
Default http://www.tei-c.org/ns/1.0
Note When specified on an <elementSpec>, this attribute specifies the namespace of the element being added, deleted, replaced, or changed. When specified on a <schemaSpec>, this attribute specifies the namespace of every element that is added, deleted, replaced, or changed by <elementSpec> children of the <schemaSpec>, or by <elementSpec>s referred to by <specGrpRef> children of the <schemaSpec>, *unless* overridden by an *ns* attribute on the <elementSpec>.
Note that the value of *ns* of <attDef> is *not* inherited from its ancestors.

---

att.naming provides attributes common to elements which refer to named persons, places, organizations etc. [*3.6.1. Referring Strings 14.3.7. Names and Nyms*]

Module tei — The TEI Infrastructure

Members att.personal[addName eventName forename genName name objectName orgName persName placeName roleName surname] affiliation author birth bloc climate collection country death district editor education event geogFeat geogName institution nationality occupation offset origPlace population pubPlace region repository residence rs settlement socecStatus state terrain trait

Attributes
- att.canonical
  - *@key*
  - *@ref*

`@role` may be used to specify further information about the entity referenced by this name in the form of a set of whitespace-separated values, for example the occupation of a person, or the status of a place.
Status Optional
Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace

`@nymRef` (reference to the canonical name) provides a means of locating the canonical form (*nym*) of the names associated with the object named by the element bearing it.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace
Note The value must point directly to one or more XML elements by means of one or more URIs, separated by whitespace. If more than one is supplied, the implication is that the name is associated with several distinct canonical names.

---

att.notated provides attributes to indicate any specialised notation used for element content.

Module tei — The TEI Infrastructure

Members c cl formula hyph listAnnotation m oRef orth pRef phr pron quote s seg stress syll u w

Attributes

`@notation` names the notation used for the content of the element.
Status Optional
Datatype teidata.enumerated

---

att.partials provides attributes for describing the extent of lexical references for a dictionary term.

Module tei — The TEI Infrastructure

Members orth pron

Attributes

`@extent` indicates whether the pronunciation or orthography applies to all or part of a word.

Status Optional

Datatype teidata.enumerated

Suggested values include: **full** (full form)

pref (prefix)

suff (suffix)

inf (infix)

part (partial)

Note This attribute is optional, and no default value is specified, so it can be omitted if this information is not necessary.

---

att.patternReplacement provides attributes for regular-expression matching and replacement. [*17.2.3. Using Abbreviated Pointers 2.3.6.3. Milestone Method 2.3.6. The Reference System Declaration 2.3.6.2. Search-and-Replace Method*]

Module header — The TEI Header

Members cRefPattern prefixDef

Attributes

`@matchPattern` specifies a regular expression against which the values of other attributes can be matched.

Status Required

Datatype teidata.pattern

Note The syntax used should follow that defined by W3C XPath syntax. Note that parenthesized groups are used not only for establishing order of precedence and atoms for quantification, but also for creating subpatterns to be referenced by the *replacementPattern* attribute.

`@replacementPattern` specifies a 'replacement pattern', that is, the skeleton of a relative or absolute URI containing references to groups in the *matchPattern* which, once subpattern substitution has been performed, complete the URI.

Status Required

Datatype teidata.replacement

Note The strings *$1*, *$2* etc. are references to the corresponding group in the regular expression specified by *matchPattern* (counting open parenthesis, left to right). Processors are expected to replace them with whatever matched the corresponding group in the regular expression.

If a digit preceded by a dollar sign is needed in the actual replacement pattern (as opposed to being used as a back reference), the dollar sign must be written as `%24`.

---

att.performed provides attributes to specify performance-based information.

Module drama — Performance Texts

Members actor camera caption castGroup castItem castList move role sound stage tech view

Attributes

`@perf` (performance) identifies the performance or performances in which this element occurred.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note The *perf* attribute contains one or more pointers to a canonical description of the performance, typically described by a <performance> or <event> element.

---

att.personal (attributes for components of names usually, but not necessarily, personal names) common attributes for those elements which form part of a name usually, but not necessarily, a personal name. [*14.2.1. Personal Names*]

Module tei — The TEI Infrastructure

Members addName eventName forename genName name objectName orgName persName placeName roleName surname

Attributes

- att.naming
  - *@role*
  - *@nymRef*
  - att.canonical
    - *@key*
    - *@ref*

`@full` indicates whether the name component is given in full, as an abbreviation or simply as an initial.

Status Optional

Datatype teidata.enumerated

Legal values are: **yes** (yes) the name component is spelled out in full.[Default]

abb (abbreviated) the name component is given in an abbreviated form.

init (initial letter) the name component is indicated only by one initial.

`@sort` (sort) specifies the sort order of the name component in relation to others within the name.

Status Optional

Datatype teidata.count

---

att.placement provides attributes for describing where on the source page or object a textual element appears. [*3.5.3. Additions, Deletions, and Omissions 12.3.1.4. Additions and Deletions*]

Module tei — The TEI Infrastructure

Members att.transcriptional[add addSpan del delSpan mod redo restore retrace rt subst substJoin undo] div figure fw gloss head label metamark notatedMusic note noteGrp postscript sp speaker stage trailer witDetail

Attributes

`@place` specifies where this item is placed.

Status Recommended

Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace

Suggested values include: **top** at the top of the page

bottom at the foot of the page

margin in the margin (left, right, or both)

opposite on the opposite, i.e. facing, page

overleaf on the other side of the leaf

above above the line

right to the right, e.g. to the right of a vertical line of text, or to the right of a figure

below below the line

left to the left, e.g. to the left of a vertical line of text, or to the left of a figure

end at the end of e.g. chapter or volume.

inline within the body of the text.

inspace in a predefined space, for example left by an earlier scribe.

```
<add place="margin">[An addition written in the margin]</add>
<add place="bottom opposite">[An addition written at the
foot of the current page and also on the facing page]</add>
<note place="bottom">Ibid, p.7</note>
```

---

att.pointing provides a set of attributes used by all elements which point to other elements by means of one or more URI references. [*1.3.1.1.2. Language Indicators 3.7. Simple Links and Cross-References*]

Module tei — The TEI Infrastructure

Members att.pointing.group[altGrp joinGrp linkGrp] alt annotation calendar catRef citedRange gloss join licence link locus note noteGrp oRef pRef ptr ref span substJoin term witDetail

Attributes

`@targetLang` specifies the language of the content to be found at the destination referenced by *target*, using a 'language tag' generated according to BCP 47.

Status Optional

Datatype teidata.language

Schematron <sch:rule context="tei:*[not(self::tei:schemaSpec)][@targetLang]"> <sch:assert test="@target">@targetLang should only be used on «sch:name/» if @target is specified.</sch:assert> </sch:rule>

```
<linkGrp xml:id="pol-swh_aln_2.1-linkGrp">
  <ptr xml:id="pol-swh_aln_2.1.1-ptr"
    target="pol/UDHR/text.xml#pol_txt_1-head"
    type="tuv"
    targetLang="pl"/>
  <ptr xml:id="pol-swh_aln_2.1.2-ptr"
    target="swh/UDHR/text.xml#swh_txt_1-head"
    type="tuv"
    targetLang="sw"/>
</linkGrp>In the example above, the <linkGrp> combines pointers
at parallel fragments of the Universal Declaration of Human
Rights: one of them is in Polish, the other in Swahili.
```

Note The value must conform to BCP 47. If the value is a private use code (i.e., starts with x- or contains -x-), a <language> element with a matching value for its *ident* attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their (IETF) Internet Engineering Task Force definitions.

`@target` specifies the destination of the reference by supplying one or more URI References.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note One or more syntactically valid URI references, separated by whitespace. Because whitespace is used to separate URIs, no whitespace is permitted inside a single URI. If a whitespace character is required in a URI, it should be escaped with the normal mechanism, e.g. `TEI%20Consortium`.

`@evaluate` (evaluate) specifies the intended meaning when the target of a pointer is itself a pointer.
Status Optional
Datatype teidata.enumerated
Legal values are: **all** if the element pointed to is itself a pointer, then the target of that pointer will be taken, and so on, until an element is found which is not a pointer.
one if the element pointed to is itself a pointer, then its target (whether a pointer or not) is taken as the target of this pointer.
none no further evaluation of targets is carried out beyond that needed to find the element specified in the pointer's target.
Note If no value is given, the application program is responsible for deciding (possibly on the basis of user input) how far to trace a chain of pointers.

---

att.pointing.group provides a set of attributes common to all elements which enclose groups of pointer elements. [*17. Linking, Segmentation, and Alignment*]
Module tei — The TEI Infrastructure
Members altGrp joinGrp linkGrp
Attributes
- att.pointing
  - *@targetLang*
  - *@target*
  - *@evaluate*
- att.typed
  - *@type*
  - *@subtype*

`@domains` optionally specifies the identifiers of the elements within which all elements indicated by the contents of this element lie.
Status Optional
Datatype 2–∞ occurrences of teidata.pointer separated by whitespace
Note If this attribute is supplied every element specified as a target must be contained within the element or elements named by it. An application may choose whether or not to report failures to satisfy this constraint as errors, but may not access an element of the right identifier but in the wrong context. If this attribute is not supplied, then target elements may appear anywhere within the target document.
`@targFunc` (target function) describes the function of each of the values of the *target* attribute of the enclosed <link>, <join>, or <alt> tags.
Status Optional
Datatype 2–∞ occurrences of teidata.word separated by whitespace
Note The number of separate values must match the number of values in the *target* attribute in the enclosed <link>, <join>, or <alt> tags (an intermediate <ptr> element may be needed to accomplish this). It should also match the number of values in the *domains* attribute, of the current element, if one has been specified.

---

att.predicate provides attributes for filtering by an XPath predicate expression. [*23.4. Common Elements 23.5.4.1. The TEI processing model 23.5.4.9. Implementation of Processing Models*]
Module tagdocs — Documentation Elements
Members equiv model

Attributes

`@predicate` the condition under which the element bearing this attribute applies, given as an XPath predicate expression.

Status Optional

Datatype teidata.xpath

Note The XPath predicate expression given as the value of the *predicate* attribute has to be provided *without* wrapping square brackets.

Example

```
<model predicate="parent::person"
  behaviour="inline">
  <desc versionDate="2015-08-21"
    xml:lang="en">If it is a child of a person element, treat as inline</desc>
</model>
```

Example The following example declares that the <name> element can be mapped to, or is equivalent to, the external concepts of 'PERSON' and 'PLACE' depending on the 'XPath' expression given in *predicate*

```
<elementSpec ident="name" mode="change">
  <equiv name="PERSON"
    predicate="@type eq 'person'"
    uri="http://www.example.com/entities/person"/>
  <equiv name="PLACE"
    predicate="@type eq 'place'"
    uri="http://www.example.com/entities/place"/>
</elementSpec>
```

---

att.ranging provides attributes for describing numerical ranges.

Module tei — The TEI Infrastructure

Members att.dimensions[att.damaged[damage damageSpan] add addSpan age birth date death del delSpan depth dim dimensions ellipsis ex floruit gap geogFeat height mod offset origDate population redo restore retrace secl space state subst substJoin supplied surplus time trait unclear undo width] measure num precision

Attributes

`@atLeast` gives a minimum estimated value for the approximate measurement.

Status Optional

Datatype teidata.numeric

`@atMost` gives a maximum estimated value for the approximate measurement.

Status Optional

Datatype teidata.numeric

`@min` where the measurement summarizes more than one observation or a range, supplies the minimum value observed.

Status Optional

Datatype teidata.numeric

`@max` where the measurement summarizes more than one observation or a range, supplies the maximum value observed.

Status Optional

Datatype teidata.numeric

`@confidence` specifies the degree of statistical confidence (between zero and one) that a value falls within the range specified by *min* and *max*, or the proportion of observed values that fall within that range.

Status Optional

Datatype teidata.probability

Example

```
 The MS. was lost in transmission by mail from
<del  rend="overstrike">
  <gap  reason="illegible"
    extent="one or two letters"  atLeast="1"  atMost="2"  unit="chars"/>
</del>
Philadelphia to the Graphic office, New York.
```

Example

```
 Americares has been supporting the health sector in Eastern Europe since 1986,
and since 1992 has provided <measure  atLeast="120000000"  unit="USD"
  commodity="currency">more
than $120m</measure> in aid to Ukrainians.
```

---

att.rdgPart provides attributes to mark the beginning or ending of a fragmentary manuscript or other witness. [*13.1.5. Fragmentary Witnesses*]

Module textcrit — Critical Apparatus

Members lacunaEnd lacunaStart wit witEnd witStart

Attributes

`@wit` (witness or witnesses) contains a space-delimited list of one or more sigla indicating the witnesses to this reading beginning or ending at this point.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

These elements may appear anywhere within the elements <lem> and <rdg>, and also within any of their constituent elements.

---

att.repeatable provides attributes for the elements which define component parts of a content model.

Module tagdocs — Documentation Elements

Members alternate anyElement classRef datatype elementRef interleave sequence

Attributes

`@minOccurs` (minimum number of occurrences) indicates the smallest number of times this component may occur.

Status Optional

Datatype teidata.count

Default 1

`@maxOccurs` (maximum number of occurrences) indicates the largest number of times this component may occur.

Status Optional

Datatype teidata.unboundedCount

Default 1

Schematron <sch:rule context="tei:*[@minOccurs and @maxOccurs]"> <sch:let name="min" value="@minOccurs cast as xs:integer"/> <sch:let name="max" value="if (normalize-space(

@maxOccurs) eq 'unbounded') then -1 else @maxOccurs cast as xs:integer"/> <sch:assert test="$max eq -1 or $max ge $min">@maxOccurs should be greater than or equal to @minOccurs.</sch:assert> </sch:rule> <sch:rule context="tei:*[@minOccurs and not(@maxOccurs)]"> <sch:assert test="@minOccurs cast as xs:integer lt 2">When @maxOccurs is not specified, @minOccurs must be 0 or 1.</sch:assert> </sch:rule>

Note The value of *minOccurs* must always be less than or equal to that of *maxOccurs*. Since the default value of *maxOccurs* is 1, when *maxOccurs* is not specified *minOccurs* must always be less than or equal to 1. The default value of *minOccurs* is also 1, and therefore, when *minOccurs* is not specified the value of *maxOccurs* must always be greater than or equal to 1. An ODD processor should raise an error if either of these conditions is not met.

---

att.resourced provides attributes by which a resource (such as an externally held media file) may be located.

Module tei — The TEI Infrastructure

Members graphic media schemaRef

Attributes

`@url` (uniform resource locator) specifies the URL from which the media concerned may be obtained.

Status Required

Datatype teidata.pointer

---

att.scope provides attributes to describe, in general terms, the scope of an element's application.

Module tei — The TEI Infrastructure

Members att.handFeatures[handNote handShift scriptNote typeNote] language

Attributes

`@scope` indicates the scope of application of the element

Status Optional

Datatype teidata.enumerated

Suggested values include: **sole** only this particular feature is used throughout the document

major this feature is used through most of the document

minor this feature is used occasionally through the document

```
<langUsage>
  <language ident="en"
    scope="major"/>
  <language ident="es"
    scope="minor"/>
  <language ident="x-ww"
    scope="minor">An invented language the children call
<name>Wikwah</name>.</language>
</langUsage>
<handNote scope="sole">
  <p>Written in insular phase II half-uncial with
     interlinear Old English gloss in an Anglo-Saxon
     pointed minuscule.</p>
</handNote>
```

---

att.scoping provides attributes for selecting particular elements within a document.

Module tei — The TEI Infrastructure

Members certainty precision respons

Attributes

`@target` points at one or more sets of zero or more elements each.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

```
Elizabeth went to <persName xml:id="ESSEX">Essex</persName>
<certainty target="#ESSEX"
  locus="name"
  degree="0.6"/>
```

`@match` supplies an XPath selection pattern using the syntax defined in **?** which identifies a set of nodes, selected within the context identified by the *target* attribute if this is supplied, or within the context of the parent element if it is not.

Status Optional

Datatype teidata.xpath

```
<gap reason="cancelled">
  <certainty match="@reason"
    locus="value"
    cert="low"/>
</gap>
```

The semantics of this element apply to the nodeset identified by the value of the *target* attribute, possibly modified by the value of the *match* attribute. If more than one identifier is given, the implication is that all elements (or nodesets) are intended. The *match* attribute may also be used as a means of identifying groups of elements.

If *target* and *match* are present, *target* selects an element and the XPath expression in *match* is evaluated in the context of that element. If neither attribute is present, the expression applies to its parent element. If only *target* is given, the expression refers to the selected element or nodeset. If only *match* is given, the XPath expression is evaluated in the context of the parent element of the bearing element.

Note that the value of the *target* attribute may include an XPointer expression including an XPath expression (see *17.2.4. TEI XPointer Schemes*).

---

att.segLike

provides attributes for elements used for arbitrary segmentation. [*17.3. Blocks, Segments, and Anchors 18.1. Linguistic Segment Categories*]

Module tei — The TEI Infrastructure

Members c cl m pc phr s seg w

Attributes

- att.datcat
  - *@datcat*
  - *@valueDatcat*
  - *@targetDatcat*
- att.fragmentable
  - *@part*
- att.metrical
  - *@met*
  - *@real*
  - *@rhyme*

`@function` (function) characterizes the function of the segment.

Status Optional

Datatype teidata.enumerated

Note Attribute values will often vary depending on the type of element to which they are attached. For example, a <cl>, may take values such as coordinate, subject, adverbial etc. For a <phr>, such values as subject, predicate etc. may be more appropriate. Such constraints will typically be implemented by a project-defined customization.

---

att.sortable provides attributes for elements in lists or groups that are sortable, but whose sorting key cannot be derived mechanically from the element content. [*10.1. Dictionary Body and Overall Structure*]

Module tei — The TEI Infrastructure

Members bibl biblFull biblStruct correspAction entry entryFree event idno item list listApp listBibl listChange listEvent listNym listObject listOrg listPerson listPlace listRelation listWit msDesc nym object org person personGrp persona place relation superEntry term witness

Attributes

`@sortKey` supplies the sort key for this element in an index, list or group which contains it.

Status Optional

Datatype teidata.word

```
David's other principal backer, Josiah
ha-Kohen <index  indexName="NAMES">
  <term  sortKey="Azarya_Josiah_Kohen">Josiah ha-Kohen b.
Azarya</term>
</index> b. Azarya, son of one of the last gaons of Sura was
David's own first
cousin.
```

Note The sort key is used to determine the sequence and grouping of entries in an index. It provides a sequence of characters which, when sorted with the other values, will produced the desired order; specifics of sort key construction are application-dependent

Dictionary order often differs from the collation sequence of machine-readable character sets; in English-language dictionaries, an entry for *4-H* will often appear alphabetized under ‘fourh’, and *McCoy* may be alphabetized under ‘maccoy’, while *A1*, *A4*, and *A5* may all appear in numeric order ‘alphabetized’ between ‘a-’ and ‘AA’. The sort key is required if the orthography of the dictionary entry does not suffice to determine its location.

---

att.spanning provides attributes for elements which delimit a span of text by pointing mechanisms rather than by enclosing it. [*12.3.1.4. Additions and Deletions*]

Module tei — The TEI Infrastructure

Members addSpan cb damageSpan delSpan gb index lb metamark milestone mod pb redo retrace undo

Attributes

`@spanTo` indicates the end of a span initiated by the element bearing this attribute.

Status Optional

Datatype teidata.pointer

Schematron The @spanTo attribute must point to an element following the current element; however, this can only be tested if both this element and the one pointed to are in the same document. <sch:rule context=”tei:*[starts-with(@spanTo, ’#’)]”> <sch:assert test=”id(substring(@spanTo, 2)) » .”> The element indicated by @spanTo (<sch:value-of select=”@spanTo”/>) must follow the current «sch:name/» element. </sch:assert> </sch:rule>

The span is defined as running in document order from the start of the content of the pointing element to the end of the content of the element pointed to by the *spanTo* attribute (if any). If no value is supplied for the attribute, the assumption is that the span is coextensive with the pointing element. If no content is present, the assumption is that the starting point of the span is immediately following the element itself.

---

att.styleDef provides attributes to specify the name of a formal definition language used to provide formatting or rendition information.

Module tei — The TEI Infrastructure

Members rendition styleDefDecl

Attributes

`@scheme` identifies the language used to describe the rendition.

Status Optional

Datatype teidata.enumerated

Legal values are: **css** Cascading Stylesheet Language

xslfo Extensible Stylesheet Language Formatting Objects

free Informal free text description

other A user-defined rendition description language

Note If no value for the @scheme attribute is provided, then the default assumption should be that CSS is in use.

`@schemeVersion` supplies a version number for the style language provided in *scheme*.

Status Optional

Datatype teidata.versionNumber

Schematron <sch:rule context="tei:*[@schemeVersion]"> <sch:assert test="@scheme and not(@scheme eq 'free')"> @schemeVersion can only be used if @scheme is specified. </sch:assert> </sch:rule>

Note If *schemeVersion* is used, then *scheme* should also appear, with a value other than free.

---

att.tableDecoration provides attributes used to decorate rows or cells of a table. [*15. Tables, Formulæ, Graphics, and Notated Music*]

Module figures — Tables, Formulæ, Graphics, and Notated Music

Members cell row

Attributes

`@role` (role) indicates the kind of information held in this cell or in each cell of this row.

Status Optional

Datatype teidata.enumerated

Suggested values include: **label** labelling or descriptive information only.

data data values.[Default]

Note When this attribute is specified on a row, its value is the default for all cells in this row. When specified on a cell, its value overrides any default specified by the *role* attribute of the parent <row> element.

`@rows` (rows) indicates the number of rows occupied by this cell or row.

Status Optional

Datatype teidata.count

Default 1

Note A value greater than one indicates that this cell spans several rows. Where several cells span multiple rows, it may be more convenient to use nested tables.

`@cols` (columns) indicates the number of columns occupied by this cell or row.
Status Optional
Datatype teidata.count
Default 1
Note A value greater than one indicates that this cell or row spans several columns. Where an initial cell spans an entire row, it may be better treated as a heading.

---

att.textCritical defines a set of attributes common to all elements representing variant readings in text critical work. [*13.1. The Apparatus Entry, Readings, and Witnesses*]
Module textcrit — Critical Apparatus
Members lem rdg rdgGrp
Attributes
- att.written
  - *@hand*
- att.typed
  - ~~type~~
  - @subtype

`@type` classifies the reading according to some useful typology.
Status Optional
Datatype teidata.enumerated
Sample values include: **substantive** (substantive) the reading offers a substantive variant.
orthographic (orthographic) the reading differs only orthographically, not in substance, from other readings.

`@cause` classifies the cause for the variant reading, according to any appropriate typology of possible origins.
Status Optional
Datatype teidata.enumerated
Sample values include: **homeoteleuton**
homeoarchy
paleographicConfusion
haplography
dittography
falseEmendation

`@varSeq` (variant sequence) provides a number indicating the position of this reading in a sequence, when there is reason to presume a sequence to the variants.
Status Optional
Datatype teidata.count
Note Different variant sequences could be coded with distinct number trails: 1-2-3 for one sequence, 5-6-7 for another. More complex variant sequences, with (for example) multiple branchings from single readings, may be expressed through the <join> element.

`@require` points to other readings that are required when adopting the current reading or lemma.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

This element class defines attributes inherited by <rdg>, <lem>, and <rdgGrp>.

---

att.timed provides attributes common to those elements which have a duration in time, expressed either absolutely or by reference to an alignment map. [*8.3.5. Temporal Information*]

Module tei — The TEI Infrastructure

Members annotationBlock binaryObject ellipsis gap incident kinesic media pause post u vocal writing

Attributes
- att.duration
  - att.duration.iso
    - *@dur-iso*
  - att.duration.w3c
    - *@dur*

`@start` indicates the location within a temporal alignment at which this element begins.
Status Optional
Datatype teidata.pointer
Note If no value is supplied, the element is assumed to follow the immediately preceding element at the same hierarchic level.

`@end` indicates the location within a temporal alignment at which this element ends.
Status Optional
Datatype teidata.pointer
Note If no value is supplied, the element is assumed to precede the immediately following element at the same hierarchic level.

---

att.transcriptional provides attributes specific to elements encoding authorial or scribal intervention in a text when transcribing manuscript or similar sources. [*12.3.1.4. Additions and Deletions*]

Module tei — The TEI Infrastructure

Members add addSpan del delSpan mod redo restore retrace rt subst substJoin undo

Attributes
- att.editLike
  - *@evidence*
  - *@instant*
- att.placement
  - *@place*
- att.written
  - *@hand*

`@status` indicates the effect of the intervention, for example in the case of a deletion, strikeouts which include too much or too little text, or in the case of an addition, an insertion which duplicates some of the text already present.
Status Optional
Datatype teidata.enumerated
Sample values include: **duplicate** all of the text indicated as an addition duplicates some text that is in the original, whether the duplication is word-for-word or less exact.
duplicate-partial part of the text indicated as an addition duplicates some text that is in the original
excessStart some text at the beginning of the deletion is marked as deleted even though it clearly should not be deleted.
excessEnd some text at the end of the deletion is marked as deleted even though it clearly should not be deleted.
shortStart some text at the beginning of the deletion is not marked as deleted even though it clearly should be.

shortEnd some text at the end of the deletion is not marked as deleted even though it clearly should be.

partial some text in the deletion is not marked as deleted even though it clearly should be.

unremarkable the deletion is not faulty.[Default]

Note Status information on each deletion is needed rather rarely except in critical editions from authorial manuscripts; status information on additions is even less common.

Marking a deletion or addition as faulty is inescapably an interpretive act; the usual test applied in practice is the linguistic acceptability of the text with and without the letters or words in question.

`@cause` documents the presumed cause for the intervention.

Status Optional

Datatype teidata.enumerated

`@seq` (sequence) assigns a sequence number related to the order in which the encoded features carrying this attribute are believed to have occurred.

Status Optional

Datatype teidata.count

---

att.translatable provides attributes used to indicate the status of a translatable portion of an ODD document.

Module tagdocs — Documentation Elements

Members desc exemplum gloss remarks valDesc

Attributes

`@versionDate` specifies the date on which the source text was extracted and sent to the translator

Status Optional

Datatype teidata.temporal.working

Note The *versionDate* attribute can be used to determine whether a translation might need to be revisited, by comparing the modification date on the containing file with the *versionDate* value on the translation. If the file has changed, changelogs can be checked to see whether the source text has been modified since the translation was made.

---

att.typed provides attributes that can be used to classify or subclassify elements in any way. [*1.3.1. Attribute Classes 18.1.1. Words and Above 3.6.1. Referring Strings 3.7. Simple Links and Cross-References 3.6.5. Abbreviations and Their Expansions 3.13.1. Core Tags for Verse 7.2.6. Speech Contents 4.1.1. Un-numbered Divisions 4.1.2. Numbered Divisions 4.2.1. Headings and Trailers 4.4. Virtual Divisions 14.3.2.3. Personal Relationships 12.3.1.1. Core Elements for Transcriptional Work 17.1.1. Pointers and Links 17.3. Blocks, Segments, and Anchors 13.2. Linking the Apparatus to the Text 23.5.1.2. Defining Content Models: RELAX NG 8.3. Elements Unique to Spoken Texts 24.3.1.3. Modification of Attribute and Attribute Value Lists*]

Attributes

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

Status Optional

Datatype teidata.enumerated

```
<div type="verse">
  <head>Night in Tarras</head>
  <lg type="stanza">
    <l>At evening tramping on the hot white road</l>
    <l>…</l>
  </lg>
  <lg type="stanza">
    <l>A wind sprang up from nowhere as the sky</l>
    <l>…</l>
  </lg>
</div>
```

Note The *type* attribute is present on a number of elements, not all of which are members of att.typed, usually because these elements restrict the possible values for the attribute in a specific way.

`@subtype` (subtype) provides a sub-categorization of the element, if needed.

Status Optional

Datatype teidata.enumerated

Note The *subtype* attribute may be used to provide any sub-classification for the element additional to that provided by its *type* attribute.

Schematron <sch:rule context="tei:*[@subtype]"> <sch:assert test="@type"> The «sch:name/» element should not be categorized in detail with @subtype unless also categorized in general with @type. </sch:assert> </sch:rule>

Note When appropriate, values from an established typology should be used. Alternatively a typology may be defined in the associated TEI header. If values are to be taken from a project-specific list, this should be defined using the <valList> element in the project-specific schema description, as described in *24.3.1.3. Modification of Attribute and Attribute Value Lists* .

---

att.witnessed provides attributes used to identify the witnesses supporting a particular reading in a critical apparatus. [*13.1. The Apparatus Entry, Readings, and Witnesses*]

Module textcrit — Critical Apparatus

Members lem rdg

Attributes

`@wit` (witness or witnesses) contains a space-delimited list of one or more pointers indicating the witnesses which attest to a given reading.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note If the apparatus contains readings only for a single witness, this attribute may be consistently omitted.

This attribute may occur both within an apparatus gathering variant readings in the transcription of an individual witness and within an apparatus gathering readings from different witnesses.

Additional descriptions or alternative versions of the sigla referenced may be supplied as the content of a child <wit> element.

---

att.written provides attributes to indicate the hand in which the content of an element was written in the source being transcribed. [*1.3.1. Attribute Classes*]

Module tei — The TEI Infrastructure

Members att.damaged[damage damageSpan] att.textCritical[lem rdg rdgGrp] att.transcriptional[add addSpan del delSpan mod redo restore retrace rt subst substJoin undo] ab closer dateline div emph figure fw head hi label line note noteGrp opener p path postscript salute seg signed sp speaker stage text trailer zone

Attributes

`@hand` points to a <handNote> element describing the hand considered responsible for the content of the element concerned.

Status Optional

Datatype teidata.pointer

C Elements

C.1 About the Elements Appendix

This appendix gives you links to reference pages for all elements in the TEI Guidelines. There are 588 TEI elements in revision 113e933e2 of TEI P5 Version 4.12.0 of the TEI Guidelines.

The elements listed here are in the TEI Namespace: http://www.tei-c.org/ns/1.0 unless otherwise noted on that element's reference page.

<ab> (anonymous block) contains any component-level unit of text, acting as a container for phrase or inter level elements analogous to, but without the same constraints as, a paragraph. [*17.3. Blocks, Segments, and Anchors*]

character data

Note The <ab> element may be used at the encoder's discretion to mark any component-level elements in a text for which no other more specific appropriate markup is defined. Unlike paragraphs, <ab> may nest and may use the *type* and *subtype* attributes.

Example

```
<div  type="book"  n="Genesis">
  <div  type="chapter"  n="1">
    <ab>In the beginning God created the heaven and the earth.</ab>
    <ab>And the earth was without form, and void; and
        darkness was upon the face of the deep. And the
        spirit of God moved upon the face of the waters.</ab>
    <ab>And God said, Let there be light: and there was light.</ab>
<!-- ...-->
  </div>
</div>
```

Schematron <sch:rule context="tei:l//tei:ab"> <sch:assert test="ancestor::tei:floatingText | parent::tei:figure | parent::tei:note"> Abstract model violation: Metrical lines (<l> elements) may not contain higher-level divisions such as <p> or <ab>, unless <ab> is a child of <figure> or <note>, or is a descendant of <floatingText>. </sch:assert> </sch:rule>

Content model

```
<content>
 <macroRef key="macro.abContent"/>
</content>
```

Schema Declaration

```

    - *@source*
- att.cmc
  - *@generatedBy*

- att.typed
  - ~~type~~
  - @subtype

`@type` (type) allows the encoder to classify the abbreviation according to some convenient typology.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Sample values include: **suspension** (suspension) the abbreviation provides the first letter(s) of the word or phrase, omitting the remainder.
contraction (contraction) the abbreviation omits some letter(s) in the middle.
brevigraph the abbreviation comprises a special symbol or mark.
superscription (superscription) the abbreviation includes writing above the line.
acronym (acronym) the abbreviation comprises the initial letters of the words of a phrase.
title (title) the abbreviation is for a title of address (Dr, Ms, Mr, ...)
organization (organization) the abbreviation is for the name of an organization.
geographic (geographic) the abbreviation is for a geographic name.
Note The *type* attribute is provided for the sake of those who wish to classify abbreviations at their point of occurrence; this may be useful in some circumstances, though usually the same abbreviation will have the same type in all occurrences. As the sample values make clear, abbreviations may be classified by the method used to construct them, the method of writing them, or the referent of the term abbreviated; the typology used is up to the encoder and should be carefully planned to meet the needs of the expected use. For a typology of Middle English abbreviations, see **?**

Note This element is intended only for cases where no abstract is available in the original source. Any abstract already present in the source document should be encoded as a within the <front>, as it should for a born-digital document.

Example

```
<profileDesc>
  <abstract  resp="#LB">
    <p>Good database design involves the acquisition and deployment of
        skills which have a wider relevance to the educational process. From
        a set of more or less instinctive rules of thumb a formal discipline
        or "methodology" of database design has evolved. Applying that
        methodology can be of great benefit to a very wide range of academic
        subjects: it requires fundamental skills of abstraction and
        generalisation and it provides a simple mechanism whereby complex
        ideas and information structures can be represented and manipulated,
        even without the use of a computer. </p>
  </abstract>
</profileDesc>

character data

Note In a diplomatic edition attempting to represent an original source, the <add> element should not be used for additions to the current TEI electronic edition made by editors or encoders. In these cases, either the <corr> or <supplied> element are recommended.

In a TEI edition of a historical text with previous editorial emendations in which such additions or reconstructions are considered part of the source text, the use of <add> may be appropriate, dependent on the editorial philosophy of the project.

Example

```
The story I am
going to relate is true as to its main facts, and as to the
```

```
consequences <add  place="above">of these facts</add> from which
this tale takes its title.
```

  - *@generatedBy*
- att.typed
  - ~~type~~
  - @subtype

`@type` characterizes the address in some sense, using any convenient classification scheme or typology.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Suggested values include: **billing** the address to which a bill for goods or services should be sent.
delivery the address to which packages should be sent via a private delivery service.
mailing the address to which mail should be sent via a public postal service.
military the address to which mail to deployed military personnel should be sent.
physical the address of a building irrespective of where mail to its occupants should be sent (for example, for the fire department).

`@role` specifies further information about the purpose of the address.

Status Optional

Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace

Sample values include: **sender** the address of the sender of a piece of correspondence.

return the address to which undeliverable mail should be returned.

recipient the address of the intended recipient of a piece of correspondence.

work the address to which work-related mail should be sent, typically that of the recipient's employer.

home the address to which non-work-related mail should be sent, typically the domicile of the recipient.

start the address of the beginning of a route, for example of a race.

finish the address of the end of a route, for example of a race.

pickup the address at which a person or package is picked up, for example by a taxi or delivery service.

dropOff the address at which a person or package is dropped off, for example by a taxi or delivery service.

Note Whereas *type* is used to differentiate the kind of address (e.g. a street address vs. a post office box, or a physical address vs. a mailing address), *role* is used to differentiate the purpose of the address, for example within a correspondence ecosystem (e.g. the address of the sender vs. that of the intended recipient, or a college student's permanent address vs. address while at school).

Note This element should be used for postal addresses only. Within it, the generic element <addrLine> may be used as an alternative to any of the more specialized elements available from the `model.addrPart` class, such as <street>, <postCode> etc.

Example Using just the elements defined by the core module, an address could be represented as follows:

```
<address>
  <street>via Marsala 24</street>
  <postCode>40126</postCode>
  <name>Bologna</name>
  <name>Italy</name>
</address>
```

Example When a schema includes the names and dates module more specific elements such as country or settlement would be preferable over generic <name>:

```
<address>
  <street>via Marsala 24</street>
  <postCode>40126</postCode>
  <settlement>Bologna</settlement>
  <country>Italy</country>
</address>
```

Example

```
<address>
  <addrLine>Computing Center, MC 135</addrLine>
  <addrLine>P.O. Box 6998</addrLine>
  <addrLine>Chicago, IL 60680</addrLine>
  <addrLine>USA</addrLine>
</address>
```

Example

```
<address>
  <country key="FR"/>
  <settlement type="city">Lyon</settlement>
  <postCode>69002</postCode>
  <district type="arrondissement">IIème</district>
  <district type="quartier">Perrache</district>
  <street>
    <num>30</num>, Cours de Verdun</street>
</address>
```

Content model

```
<content>
 <sequence>
  <classRef key="model.global"
   minOccurs="0" maxOccurs="unbounded"/>
  <sequence minOccurs="1"
   maxOccurs="unbounded">
   <classRef key="model.addrPart"/>

character data

Note Addresses may be encoded either as a sequence of lines, or using any sequence of component elements from the `model.addrPart` class. Other non-postal forms of address, such as telephone numbers or email, should not be included within an <address> element directly but may be wrapped within an <addrLine> if they form part of the printed address in some source text.

Example

```
<address>
  <addrLine>Computing Center, MC 135</addrLine>
  <addrLine>P.O. Box 6998</addrLine>
  <addrLine>Chicago, IL</addrLine>
  <addrLine>60680 USA</addrLine>
</address>
```

Example

```
<addrLine>
  <ref  target="tel:+1-201-555-0123">(201) 555 0123</ref>
</addrLine>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element addrLine
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   macro.phraseSeq}
```

<addSpan> (added span of text) marks the beginning of a longer sequence of text added by an author, scribe, annotator or corrector (see also <add>). [*12.3.1.4. Additions and Deletions*]

character data

Note If included, the name of an organization may be tagged using either the <name> element as above, or the more specific <orgName> element.

Example

```
<affiliation>Junior project officer for the US <name  type="org">National
Endowment for
    the Humanities</name>
</affiliation>
```

Example This example indicates that the person was affiliated with the Australian Journalists Association at some point between the dates listed.

```
<affiliation  notAfter="1960-01-01"
  notBefore="1957-02-28">Paid up member of the
<orgName>Australian Journalists Association</orgName>
</affiliation>
```

Example This example indicates that the person was affiliated with Mount Holyoke College throughout the entire span of the date range listed.

```
<affiliation  from="1902-01-01"

  - ~~type~~
  - @subtype

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.
Derived from att.typed
Status Optional
Datatype teidata.enumerated

Sample values include: **western**

sui

subjective

objective

inWorld (in world) age of a fictional character at the time the story takes place, rather than at the time the story is told

chronological

biological

psychological

functional

`@value` supplies a numeric code representing the age or age group.

Status Optional

Datatype teidata.count

Note This attribute may be used to complement a more detailed discussion of a person's age in the content of the element

Member of model.persStateLike

character data

Note As with other culturally-constructed traits such as sex, the way in which this concept is described in different cultural contexts may vary. The normalizing attributes are provided as a means of simplifying that variety to Western European norms and should not be used where that is inappropriate. The content of the element may be used to describe the intended concept in more detail, using plain text.

Example

```
<age value="2" notAfter="1986">under 20 in the early eighties</age>
```

Content model

```
<content>
```

```
 <macroRef key="macro.phraseSeq.limited"/>
</content>
```

Schema Declaration

```

  - – *@generatedBy*
- att.typed
  - – *@type*
  - – *@subtype*
- att.pointing
  - – ~~target~~
  - – @targetLang
  - – @evaluate

`@target` specifies the destination of the reference by supplying one or more URI References.
Derived from att.pointing
Status Optional
Datatype 2–∞ occurrences of teidata.pointer separated by whitespace

`@mode` states whether the alternations gathered in this collection are exclusive or inclusive.
Status Recommended
Datatype teidata.enumerated
Legal values are: **excl** (exclusive) indicates that the alternation is exclusive, i.e. that at most one of the alternatives occurs.
incl (inclusive) indicates that the alternation is not exclusive, i.e. that one or more of the alternatives occur.

`@weights` If *mode* is excl, each weight states the probability that the corresponding alternative occurs. If *mode* is incl each weight states the probability that the corresponding alternative occurs given that at least one of the other alternatives occurs.
Status Optional
Datatype 2–∞ occurrences of teidata.probability separated by whitespace
Note If *mode* is excl, the sum of weights must be 1. If *mode* is incl, the sum of weights must be in the range from 0 to the number of alternants.

Contained by biblStruct

May contain

core: author date editor ptr ref respStmt textLang title

header: availability idno

tagdocs: listRef

Note May contain titles and statements of responsibility (author, editor, or other), in any order.

The <analytic> element may only occur within a <biblStruct>, where its use is mandatory for the description of an analytic level bibliographic item.

Example

```
<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title>Historical Editions in the States</title>
  </analytic>
  <monogr>
    <title  level="j">Computers and the Humanities</title>
    <imprint>
      <date  when="1991-12">(December, 1991):</date>
    </imprint>
    <biblScope>25.6</biblScope>
    <biblScope>377–380</biblScope>
```

```
      </monogr>
    </biblStruct>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <elementRef key="author"/>
  <elementRef key="editor"/>
  <elementRef key="respStmt"/>
  <elementRef key="title"/>

May contain Empty element

Note On this element, the global *xml:id* attribute must be supplied to specify an identifier for the point at which this element occurs within a document. The value used may be chosen freely provided that it is unique within the document and is a syntactically valid name. There is no requirement for values containing numbers to be in sequence.

Example

```
<s>The anchor is he<anchor  xml:id="A234"/>re somewhere.</s>
<s>Help me find it.<ptr  target="#A234"/>
</s>
```

Content model `<content> <empty/></content>`

Schema Declaration

  - @exclude
  - @select
- att.global.rendition
  - @rend
  - @style
  - @rendition
- att.global.responsibility
  - @cert
  - @resp
- att.global.source
  - @source
- att.pointing
  - ~~target~~
  - @targetLang
  - @evaluate

`@xml:id` (identifier) provides a unique identifier for the element bearing the attribute.
Derived from att.global
Status Required
Datatype ID

`@target` specifies the destination of the reference by supplying one or more URI References.
Derived from att.pointing
Status Required
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@motivation` *Status* Optional
Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace
Legal values are: **assessing** intent is to assess the target resource in some way, rather than simply make a comment about it
bookmarking intent is to create a bookmark to the target or part thereof
classifying intent is to classify the target in some way

commenting intent is to comment about the target

describing intent is to describe the target, rather than (for example) comment on it

editing intent is to request an edit or a change to the target resource

highlighting intent is to highlight the target resource or a segment thereof

identifying intent is to assign an identity to the target

linking intent is to link to a resource related to the target

moderating intent is to assign some value or quality to the target

questioning intent is to ask a question about the target

replying intent is to reply to a previous statement, either an annotation or another resource

tagging intent is to associate a tag with the target

Note For further detailed explanation of the suggested values, see the Web Annotation Vocabulary (WAV). The motivations described here map to URIs defined by the WAV and when exported to RDF or JSON-LD must have the URI `http://www.w3.org/ns/oa#` prepended.

As an RDF vocabulary, WADM permits the definition of new motivations (see Appendix C of the WAV). In TEI, new motivations may be defined in a custom ODD (see section 23.3.1.3). New motivations must also map to URIs defined by an RDF ontology extending the WAV.

`@require` supplies a list of namespaces to one of which the permitted elements must belong.
Status Optional
Datatype 1–∞ occurrences of teidata.namespace separated by whitespace

`@except` supplies a list of namespaces or prefixed element names which are not permitted.
Status Optional
Datatype 1–∞ occurrences of teidata.namespaceOrName separated by whitespace
Note When RELAX NG DTD Compatibility Mode is turned on, validation requires that any elements which may take an *xml:id* be excluded from the content of `anyName` name classes. For normal TEI purposes, this includes anything in the TEI namespace and the <egXML> element. Default elements and namespaces to be excluded are set on the *defaultExceptions* attribute of the <schemaSpec>. *except* may be used when the exceptions need to be locally specified. Element prefixes must be declared using a namespace declaration on the parent or an ancestor element.

Member of model.contentPart
Contained by
tagdocs: alternate content interleave sequence
May contain Empty element
Example

```
<content>
  <anyElement  except="http://www.tei-c.org/ns/1.0"/>
</content>
```

This <content> element permits one occurrence of any element which does not belong to the TEI namespace.

Example

```
<content>
  <anyElement  minOccurs="1"
    maxOccurs="unbounded"
    require="http://www.w3.org/1998/Math/MathML
http://www.tei-c.org/ns/Examples/1.0"/>
</content>
```

This <content> element permits one or more elements which belong either to the MathML namespace or to the TEI examples namespace.

Example

```
<content>
  <alternate  minOccurs="1"
    maxOccurs="unbounded">
    <textNode/>
    <anyElement  require="http://www.tei-c.org/ns/Examples/1.0"/>
  </alternate>
</content>
```

This <content> element permits one or more children which are either text nodes or elements from the TEI examples namespace. It is the equivalent of the content model ANY in an XML DTD using the TEI All schema.

Content model `<content> <empty/></content>`

Schema Declaration

```
element anyElement
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.repeatable.attributes,
   attribute require { list { + } }?,
   attribute except { list { + } }?,
   empty
}
```

<app> (apparatus entry) contains one entry in a critical apparatus, with an optional lemma and usually one or more readings or notes on the relevant passage. [*13.1.1. The Apparatus Entry*]

Module textcrit — Critical Apparatus

Attributes • att.global

- *@xml:id*
- *@n*
- *@xml:lang*
- *@xml:base*
- *@xml:space*

- att.global.analytic
  - *@ana*
- att.global.change
  - *@change*

  - *@cert*
  - *@resp*
- att.global.source
  - *@source*

- att.typed
  - ~~type~~
  - @subtype

`@type` classifies the variation contained in this element according to some convenient typology.
Derived from att.typed
Status Optional
Datatype teidata.enumerated

`@from` identifies the beginning of the lemma in the base text.
Status Optional
Datatype teidata.pointer
Note This attribute should be used when either the double-end point method of apparatus markup, or the location-referenced method with a URL rather than canonical reference, are used.

`@to` identifies the endpoint of the lemma in the base text.

Status Optional

Datatype teidata.pointer

Note This attribute is only used when the double-end point method of apparatus markup is used, when the encoded apparatus is not embedded *in-line* in the base-text.

`@loc` (location) indicates the location of the variation, when the location-referenced method of apparatus markup is used.

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

Note This attribute is used only when the location-referenced encoding method is used. It supplies a string containing a canonical reference for the passage to which the variation applies.

`@ident` supplies an identifier for the application, independent of its version number or display name.
Status Required
Datatype teidata.name

`@version` supplies a version number for the application, independent of its identifier or display name.
Status Required
Datatype teidata.versionNumber

Member of model.applicationLike
Contained by
header: appInfo
May contain
core: desc label p ptr ref
linking: ab
tagdocs: listRef
Example

```
<appInfo>
  <application  version="1.5"
    ident="ImageMarkupTool1"  notAfter="2006-06-01">
    <label>Image Markup Tool</label>
    <ptr  target="#P1"/>
    <ptr  target="#P2"/>
  </application>
</appInfo>
```

This example shows an <appInfo> element documenting the fact that version 1.5 of the Image Markup Tool application has an interest in two parts of a document which was last saved on 06 June 2006. The parts concerned are accessible at the URLs given as the *target* attributes of the two <ptr> elements.

Content model

– att.global.rendition
* *@rend*
* *@style*
* *@rendition*

– att.global.responsibility
* *@cert*
* *@resp*

– att.global.source
* *@source*

`@from` gives the identifier of the node which is adjacent from this arc.
Status Required
Datatype teidata.pointer

`@to` gives the identifier of the node which is adjacent to this arc.
Status Required
Datatype teidata.pointer

Contained by: graph

May contain

core: label

Note The <arc> element must be used if the arcs are labeled. Otherwise, arcs can be encoded using the *adj*, *adjTo* and *adjFrom* attributes on the <node> tags in the graph. Both <arc> tags and adjacency attributes can be used, but the resulting encoding would be highly redundant.

Zero, one, or two children <label> elements may be present. The first occurrence of <label> provides a label for the arc; the second provides a second label for the arc, and should be used if a transducer is being encoded.

Example

```
<arc  from="#T3"  to="#T3">
  <label>OLD</label>
  <label>VIEUX</label>
</arc>
```

Content model

```
<content>
 <elementRef key="label" minOccurs="0"
  maxOccurs="2"/>
</content>
```

Schema Declaration

```
element arc

`@org` (organization) specifies whether only one (choice) or all (group) of the attributes in the list are available.

Status Optional

Datatype teidata.enumerated

Legal values are: **group** grouped[Default]

choice alternated

Contained by tagdocs: attList classSpec elementSpec

May contain

tagdocs: attDef attList attRef

Example

```
<attList>
  <attDef ident="type" usage="opt">
    <desc>type of schema</desc>
    <datatype>
      <dataRef key="teidata.enumerated"/>
    </datatype>
  </attDef>
</attList>
```

Example

```
<attList org="choice">
  <attDef ident="active">
    <desc versionDate="2005-07-24"
      xml:lang="en">identifies the <soCalled>active</soCalled> participants in a

character data

Note Particularly where cataloguing is likely to be based on the content of the header, it is advisable to use a generally recognized name authority file to supply the content for this element. The attributes *key* or *ref* may also be used to reference canonical information about the author(s) intended from any appropriate authority, such as a library catalogue or online resource.

In the case of a broadcast, use this element for the name of the company or network responsible for making the broadcast.

Where an author is unknown or unspecified, this element may contain text such as *Unknown* or *Anonymous*. When the appropriate TEI modules are in use, it may also contain detailed tagging of the names used for people, organizations or places, in particular where multiple names are given.

Example

```
<author>British Broadcasting Corporation</author>
<author>La Fayette, Marie Madeleine Pioche de la Vergne, comtesse de
(1634–1693)</author>
<author>Anonymous</author>
<author>Bill and Melinda Gates Foundation</author>
<author>
  <persName>Beaumont, Francis</persName>
and
<persName>John Fletcher</persName>
</author>
<author>
  <orgName  key="BBC">British Broadcasting
     Corporation</orgName>: Radio 3 Network
</author>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element author
{

character data

Note When a single page is being cited, use the *from* and *to* attributes with an identical value. When no clear

endpoint is provided, the *from* attribute may be used without *to*; for example a citation such as 'p. 3ff' might be encoded `<biblScope from="3">p. 3ff</biblScope>`.

It is now considered good practice to supply this element as a sibling (rather than a child) of <imprint>, since it supplies information which does not constitute part of the imprint.

Example

```
<biblScope>pp 12–34</biblScope>
<biblScope  unit="page"  from="12"  to="34"/>
<biblScope  unit="volume">II</biblScope>
<biblScope  unit="page">12</biblScope>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element biblScope
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.citing.attributes,
   macro.phraseSeq}
```

<biblStruct>

<biblStruct> (structured bibliographic citation) contains a structured bibliographic citation, in which only bibliographic sub-elements appear and in a specified order. [*3.12.1. - att.global.source
  - *@source*

- att.datcat
  - *@datcat*
  - *@valueDatcat*
  - *@targetDatcat*

`@value` supplies a binary value.

Status Required

Datatype teidata.truthValue

Note This attribute has a datatype of `teidata.truthValue`, which may be represented by the values 1 or true, or 0 or false.

Member of model.featureVal.single

Contained by

iso-fs: f fvLib if vAlt vColl vDefault vLabel vMerge vNot vRange

May contain Empty element

Note The value attribute may take any value permitted for attributes of the W3C datatype Boolean: this includes for example the strings `true` or `1` which are equivalent.

Example

```
<f name="strident">
  <binary value="true"/>
</f>
<f name="exclusive">
  <binary value="false"/>
</f>
```

Content model `<content> <empty/></content>`

Schema Declaration

```
element binary
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.datcat.attributes,
   attribute value { text },
   empty
}
```

<binaryObject> provides encoded binary data representing an inline graphic, audio, video or other object.

[*3.10. Graphics and Other Non-textual Components*]

`@contemporary` (contemporary) specifies whether or not the binding is contemporary with the majority of its contents.
Status Optional
Datatype teidata.xTruthValue
Note The value true indicates that the binding is contemporaneous with its contents; the value false that it is not. The value unknown should be used when the date of either binding or manuscript is unknown

Contained by: *msdescription:* bindingDesc
May contain
core: p
linking: ab
msdescription: condition decoNote
Example

```
<binding  contemporary="true">
  <p>Contemporary blind stamped leather over wooden boards with evidence of a
fore edge clasp
    closing to the back cover.</p>
</binding>
```

Example

```
<bindingDesc>
  <binding  contemporary="false">
    <p>Quarter bound by the Phillipps' binder, Bretherton, with his sticker on
the front
       pastedown.</p>
  </binding>
```

```
    <binding  contemporary="false">
      <p>Rebound by an unknown 19th c. company; edges cropped and gilt.</p>
    </binding>
  </bindingDesc>
```

Content model

}
```

<bindingDesc>

<bindingDesc> (binding description) describes the present and former bindings of a manuscript or other object, either as a series of paragraphs or as a series of distinct <binding> elements, one for each binding of the manuscript. [*11.7.3.1. Binding Descriptions*]

Module msdescription — Manuscript Description

character data

Note The byline on a title page may include either the name or a description for the document's author. Where the name is included, it may optionally be tagged using the <docAuthor> element.

Example

```
<byline>Written by a CITIZEN who continued all the
while in London. Never made publick before.</byline>
```

Example

```
<byline>Written from her own MEMORANDUMS</byline>
```

Example

```
<byline>By George Jones, Political Editor, in Washington</byline>
```

Example

```
<byline>BY
<docAuthor>THOMAS PHILIPOTT,</docAuthor>
Master of Arts,
(Somtimes)
Of Clare-Hall in Cambridge.</byline>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
  <classRef key="model.phrase"/>
  <elementRef key="docAuthor"/>
  <classRef key="model.global"/>
 </alternate>
</content>
```

Schema Declaration

```
element byline
{
   att.global.attributes,

character data

Note May contain character data and phrase-level elements. Typical values will be of the form *nominative*, *accusative*, *dative*, *genitive*, etc.

This element is synonymous with <gram type="case">.

Example Taken from *Wörterbuch der Deutschen Sprache. Veranstaltet und herausgegeben von Joachim Heinrich Campe. Erster Theil. A - bis - E. (Braunschweig 1807. In der Schulbuchhandlung)*:

Das Evangelium, des Evangelii, ...

```
<entry>
  <form type="lemma">
    <gramGrp>
      <pos value="noun"/>
      <gen value="n"/>
    </gramGrp>
    <form type="determiner">
      <orth>Das</orth>
    </form>
    <form type="headword">
      <orth>Evangelium</orth>,</form>
  </form>
  <form type="inflected">
    <gramGrp>
      <case value="genitive"/>
      <number value="singular"/>
    </gramGrp>
    <form type="determiner">
      <orth>des</orth>
    </form>
    <form type="headword">
      <orth>
        <oRef>Evangelii</oRef>,</orth>
    </form>
  </form>
</entry>

textstructure: trailer
transcr: addSpan damageSpan delSpan fw listTranspose metamark space substJoin
Note The *rend* attribute may be used, as here, to indicate whether the grouping is indicated by a brace, whitespace, font change, etc.

Note that in this example the role description 'friends of Mathias' is understood to apply to both roles equally.

Example

```
<castGroup  rend="braced">
  <castItem>
    <role>Walter</role>
    <actor>Mr Frank Hall</actor>
  </castItem>
  <castItem>
    <role>Hans</role>
    <actor>Mr F.W. Irish</actor>
  </castItem>
  <roleDesc>friends of Mathias</roleDesc>
</castGroup>
```

Content model

```
<content>
 <sequence>
  <alternate minOccurs="0"
   maxOccurs="unbounded">
   <classRef key="model.global"/>
   <classRef key="model.headLike"/>
  </alternate>
  <sequence minOccurs="1"

- att.typed
  - ~~type~~
  - @subtype

`@type` characterizes the cast item.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Legal values are: **role** the item describes a single role.[Default]
list the item describes a list of non-speaking roles.

May contain Empty element

Note On this element, the global *n* attribute indicates the number or other value associated with the column

which follows the point of insertion of this <cb> element. Encoders should adopt a clear and consistent policy as to whether the numbers associated with column beginnings relate to the physical sequence number of the column in the whole text, or whether columns are numbered within the page. The <cb> element is placed at the head of the column to which it refers.

Example Markup of an early English dictionary printed in two columns:

```
<pb/>
<cb  n="1"/>
<entryFree>
  <form>Well</form>, <sense>a Pit to hold Spring-Water</sense>:
<sense>In the Art of <hi  rend="italic">War</hi>, a Depth the Miner
    sinks into the Ground, to find out and disappoint the Enemies Mines,
    or to prepare one</sense>.
</entryFree>
<entryFree>To <form>Welter</form>, <sense>to wallow</sense>, or
<sense>lie groveling</sense>.</entryFree>
<!-- remainder of column -->
<cb  n="2"/>
<entryFree>
  <form>Wey</form>, <sense>the greatest Measure for dry Things,
    containing five Chaldron</sense>.
</entryFree>
<entryFree>
  <form>Whale</form>, <sense>the greatest of
    Sea-Fishes</sense>.
</entryFree>
```

Content model `<content> <empty/></content>`

<certainty> indicates the degree of certainty associated with some aspect of the text markup. [*22.1.2. Structured Indications of Uncertainty*]

Module certainty — Certainty, Precision, and Responsibility

Attributes • att.scoping
- *@target*
- *@match*

• att.global
- @xml:id
- @n
- @xml:lang
- @xml:base
- @xml:space

• att.global.analytic
- @ana

• att.global.change
- @change

• att.global.facs
- @facs

• att.global.linking
- @corresp
- @synch
- @sameAs
- @copyOf
- @next
- @prev
- @exclude
- @select

• att.global.rendition
- @rend
- @style
- @rendition

• att.global.responsibility
- ~~cert~~
- @resp

• att.global.source
- @source

• att.typed
- ~~type~~
- @subtype

`@cert` (certainty) signifies the degree of certainty associated with the object pointed to by the <certainty> element.
Derived from att.global.responsibility
Status Optional
Datatype teidata.certainty

`@type` characterizes the element in some sense, using any convenient classification scheme or typology; sample categorization of annotations of uncertainty might use following values:
Derived from att.typed

Status Optional

Datatype teidata.enumerated

Sample values include: **ignorance**

incompleteness

credibility

imprecision

`@locus` indicates more exactly the aspect concerning which certainty is being expressed: specifically, whether the markup is correctly located, whether the correct element or attribute name has been used, or whether the content of the element or attribute is correct, etc.

Status Required

Datatype teidata.enumerated

Legal values are: **name** uncertainty concerns whether the name of the element or attribute used is correctly applied.

start uncertainty concerns whether the start of the element is correctly identified.

end uncertainty concerns whether the end of the element is correctly identified.

location uncertainty concerns both the start and the end of the element.

value uncertainty concerns the content (for an element) or the value (for an attribute)

`@assertedValue` provides an alternative value for the aspect of the markup in question—an alternative generic identifier, transcription, or attribute value, or the identifier of an <anchor> element (to indicate an alternative starting or ending location). If an *assertedValue* is given, the confidence level specified by *degree* applies to the alternative markup specified by *assertedValue*; if none is given, it applies to the markup in the text.

Status Recommended

Datatype teidata.word

```
<certainty target="#ESX"
  locus="name"
  assertedValue="placeName"
  cert="low">
  <desc>It is unlikely, but possible, that this refers to the
place
    rather than the person.</desc>
</certainty>
```

Note This attribute makes it possible to indicate the degree of confidence in a specific alternative to some aspect of the markup. In the first example above the encoder is expressing the likelihood (.2) that the generic identifier should be <placeName> rather than <persName>, which is the coded element.

`@given` indicates one or more element(s) characterizing the conditions which are assumed in the assignment of a degree of confidence.

Status Recommended

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note The envisioned typical value of this attribute would be the identifier of another <certainty> element or a list of such identifiers. It may thus be possible to construct probability networks by chaining <certainty> elements together. Such networks would ultimately be grounded in unconditional <certainty> elements (with no value for *given*). The semantics of this chaining would be understood in this way: if a <certainty> element is specified, via a reference, as the assumption, then it is not the attribution of uncertainty that is the assumption, but rather the assertion itself. For instance, in the example above, the first <certainty> element indicates that the confidence in the identification of the new scribe as *msm*. The second indicates the degree of confidence that *Essex* is a personal name, given that the new scribe is *msm*.

Note that the given in the second <certainty> element is not the assertion that the likelihood that msm is the new scribe is 0.6, but simply the assertion that msm is the new scribe; this is a recommended convention to facilitate building networks.

The ambitious encoder may wish to attempt complex networks or probability assertions, experimenting with references to other elements or prose assertions, and deploying feature structure connectives such as <alt>, <join>, and <note>. However, we do not believe that the <certainty> element gives, at this time, a comprehensive ambiguity-free system for indicating certainty.

`@degree` indicates the degree of confidence assigned to the aspect of the markup named by the *locus* attribute.
Status Optional

```

<channel>

(primary channel) describes the medium or channel by which a text is delivered or experienced. For a written text, this might be print, manuscript, email, etc.; for a spoken one, radio, telephone, face-to-face, etc. [*16.2.1. The Text Description*]

Note Because the children of a <choice> element all represent alternative ways of encoding the same sequence, it is natural to think of them as mutually exclusive. However, there may be cases where a full representation of a text requires the alternative encodings to be considered as parallel.

Note also that <choice> elements may self-nest.

Where the purpose of an encoding is to record multiple witnesses of a single work, rather than to identify multiple possible encoding decisions at a given point, the <app> element and associated elements discussed in section *13.1. The Apparatus Entry, Readings, and Witnesses* should be preferred.

Example An American encoding of *Gulliver's Travels* which retains the British spelling but also provides a version regularized to American spelling might be encoded as follows.

```
<p>Lastly, That, upon his solemn oath to observe all the above
articles, the said man-mountain shall have a daily allowance of
meat and drink sufficient for the support of <choice>
   <sic>1724</sic>
   <corr>1728</corr>
  </choice> of our subjects,
with free access to our royal person, and other marks of our
<choice>
   <orig>favour</orig>
```

```
      <reg>favor</reg>
    </choice>.</p>
```

character data

Note When a single page is being cited, use the *from* and *to* attributes with an identical value. When no clear endpoint is provided, the *from* attribute may be used without *to*; for example a citation such as 'p. 3ff' might be encoded `<citedRange from="3">p. 3ff</citedRange>`.

Example

```
<citedRange>pp 12–13</citedRange>
<citedRange  unit="page"  from="12"  to="13"/>
<citedRange  unit="volume">II</citedRange>
<citedRange  unit="page">12</citedRange>
```

Example

```
<bibl>
  <ptr  target="#mueller01"/>,
<citedRange  target="http://example.com/mueller3.xml#page4">vol. 3, pp.
    4-5</citedRange>
</bibl>
```

Content model

`@delim` (delimiter) supplies a delimiting string preceding the structural component.

Status Optional

Datatype string

Note *delim* must contain at least one character.

`@match` (match) supplies an XPath selection pattern using the syntax defined in **?** which identifies a set of nodes which are citable structural components. The expression may be absolute (beginning with `/`) or relative. *match* on a <citeStructure> without a <citeStructure> parent must be an absolute XPath. If it is relative, its context is set by the *match* of the parent <citeStructure>.

Status Required

Datatype teidata.xpath

Schematron <sch:rule context="tei:citeStructure[not(parent::tei:citeStructure)]"> <sch:assert test="starts-with(@match,'/')">An XPath in @match on the outer «sch:name/» must start with '/'.</sch:assert> </sch:rule>

Schematron <sch:rule context="tei:citeStructure[parent::tei:citeStructure]"> <sch:assert test="not(starts-with(@match,'/'))">An XPath in @match must not start with '/' except on the outer «sch:name/».</sch:assert> </sch:rule>

`@unit` (unit) describes the structural unit indicated by the <citeStructure>.

Status Optional

Datatype teidata.enumerated

Sample values include: **book**

chapter

entry

poem

letter

line
section
verse
volume

Contained by header: citeStructure refsDecl

character data

Note The *type* attribute may be used to indicate the type of clause, taking values such as finite, nonfinite, declarative, interrogative, relative etc. as appropriate.

Example

```
<l>
  <cl  type="relative"
    function="clause_modifier">Which frightened
     both the heroes so,</cl>
</l>
<l>
  <cl>They quite forgot their quarrel.</cl>
</l>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```

`@mode` specifies the effect of this declaration on its parent module.

Status Optional

Datatype teidata.enumerated

Legal values are: **change** this declaration changes the declaration of the same name in the current definition

replace this declaration replaces the declaration of the same name in the current definition[Default]

Contained by tagdocs: classSpec elementSpec

May contain

tagdocs: memberOf

Note An empty <classes> element indicates that the element documented is not a member of any class. This should not generally happen.

Example

```
<classes>
  <memberOf  key="model.attributable"/>
  <memberOf  key="att.declarable"/>
</classes>
```

This <classes> element indicates that the element documented (which may be an element or a class) is a member of two distinct classes: `model.attributable` and `att.declarable`.

Content model

```
<content>
 <elementRef key="memberOf" minOccurs="0"
  maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element classes
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
```

```
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   attribute mode { "change" | "replace" }?,
   memberOf*
}
```

<classRef> points to the specification for an attribute or model class which is to be included in a schema. [*23.6. Class Specifications*]

Module tagdocs — Documentation Elements

    - *@rendition*
  - att.global.responsibility
    - *@cert*
    - *@resp*
  - att.global.source
    - *@source*
- att.repeatable

– *@minOccurs*

– *@maxOccurs*

`@key` the identifier used for the required class within the source indicated.

Status Required

Datatype teidata.xmlName

`@expand` indicates how references to this class within a content model should be interpreted.

Status Optional

Legal values are: **alternation** any one member of the class may appear

sequence a single occurrence of all members of the class may appear in sequence

sequenceOptional a single occurrence of one or more members of the class may appear in sequence

sequenceOptionalRepeatable one or more occurrences of one or more members of the class may appear in sequence.

sequenceRepeatable one or more occurrences of all members of the class may appear in sequence

Note If the members of the class are `a`, `b` and `c`, then a reference to the class within a content model is understood as being a reference to `a|b|c` when *expand* is omitted or has the value alternation; to `a,b,c` when it has the value sequence; to `(a?,b?,c?)` when it has the value sequenceOptional; to `(a*,b*,c*)` when it has the value sequenceOptionalRepeatable; or to `(a+,b+,c+)` when it has the value sequenceRepeatable.

`@include` supplies a list of class members which are to be included in the schema being defined.

Status Optional

Datatype 0–∞ occurrences of teidata.xmlName separated by whitespace

`@except` supplies a list of class members which are to be excluded from the schema being defined.

Status Optional

Datatype 0–∞ occurrences of teidata.xmlName separated by whitespace

Member of model.contentPart model.oddRef

Contained by

tagdocs: alternate content interleave schemaSpec sequence specGrp

May contain Empty element

Note Attribute and model classes are identified by the name supplied as value for the *ident* attribute on the <classSpec> element in which they are declared. All TEI class names are unique; attribute class names conventionally begin with the letters `att.`.

Example

```
<schemaSpec ident="myTEIe" start="TEI">
  <moduleRef key="tei"/>
  <moduleRef key="core"
    include="abbr add core addrLine address author bibl biblScope choice cit
corr date del desc divGen editor emph expan foreign gap gloss graphic head hi

  <moduleRef key="textstructure"
```

```
      include="TEI argument back body byline closer dateline div docAuthor
    docDate docEdition docImprint docTitle epigraph front group opener postscript
    salute signed text titlePage titlePart trailer"/>
     <classRef  key="att.global.facs"/>
    </schemaSpec>
```

Content model <content> <empty/></content>

Schema Declaration

```
element classRef
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.repeatable.attributes,
   attribute key { text },
   attribute expand
   {
      "alternation"
    | "sequence"
    | "sequenceOptional"
    | "sequenceOptionalRepeatable"
    | "sequenceRepeatable"
   }?,
   ( attribute include { list { * } }? | attribute except { list { * } }? ),
   empty
}
```

<classSpec>

<classSpec> (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both. [*23.3. Specification Elements 23.6. Class Specifications*]

Module tagdocs — Documentation Elements

  - ~~type~~
  - @subtype

`@type` indicates whether this is a model class or an attribute class
Derived from att.typed
Status Required
Datatype teidata.enumerated
Legal values are: **model** (content model) members of this class appear in the same content models
atts (attributes) members of this class share common attributes

`@generate` indicates which alternation and sequence instantiations of a model class may be referenced. By default, all variations are permitted.
Status Optional
Datatype 1–5 occurrences of teidata.enumerated separated by whitespace
Legal values are: **alternation** members of the class are alternatives
sequence members of the class are to be provided in sequence

sequenceOptional members of the class may be provided, in sequence, but are optional

sequenceOptionalRepeatable members of the class may be provided one or more times, in sequence, but are optional.

sequenceRepeatable members of the class may be provided one or more times, in sequence

character data

Example

```
<condition>
  <p>There are lacunae in three places in this
     manuscript. After 14v two
     leaves has been cut out and narrow strips leaves remains in the spine.
After
     68v one gathering is missing and after 101v at least one gathering of 8
leaves
     has been lost. </p>
  <p>Several leaves are damaged with tears or holes or have a
     irregular shape. Some of the damages do not allow the lines to be of full
     length and they are apparently older than the script. There are tears on
fol.
     2r-v, 9r-v, 10r-v, 15r-18v, 19r-v, 20r-22v, 23r-v, 24r-28v, 30r-v,
32r-35v,
     37r-v, 38r-v, 40r-43v, 45r-47v, 49r-v, 51r-v, 53r-60v, 67r-v, 68r-v,
70r-v,
     74r-80v, 82r-v, 86r-v, 88r-v, 89r-v, 95r-v, 97r-98v 99r-v, 100r-v. On fol.
98
```

```
      the corner has been torn off. Several leaves are in a bad condition due to
      moist and wear, and have become dark, bleached or
      wrinkled. </p>
    <p>The script has been
      touched up in the 17th century with black ink. The touching up on the
  following
      fols. was done by
    <name>Bishop Brynjólf Sveinsson</name>: 1v, 3r, 4r, 5r,
      6v, 8v,9r, 10r, 14r, 14v, 22r,30v, 36r-52v, 72v, 77r,78r,103r, 104r,. An
      AM-note says according to the lawman
    <name>Sigurður Björnsson</name> that the rest of the
      touching up was done by himself and another lawman
    <name>Sigurður Jónsson</name>.
    <name>Sigurður Björnsson</name> did the touching up
      on the following fols.: 46v, 47r, 48r, 49r-v, 50r, 52r-v.
    <name>Sigurður Jónsson</name> did the rest of the
      touching up in the section 36r-59r containing
    <title>Bretasögur</title>
    </p>
  </condition>

`@scheme` supplies the name of the language to which the declarations herein apply
Status Required
Datatype teidata.enumerated
Suggested values include: **schematron** (ISO Schematron)
Note The declarations contained in a particular <constraintDecl> (including *queryBinding*, if present) apply to the <constraintSpec> elements whose *scheme* matches the *scheme* of the <constraintDecl>.

`@queryBinding` (query language binding) specifies the query language binding for rule-based schema expressions in <constraintSpec> elements that have a matching *scheme* attribute
Status Recommended
Datatype teidata.enumerated
Suggested values include: **exslt**
stx
xslt
xslt2
xslt3
xpath
xpath2
xpath3
xpath31
xquery
xquery3
xquery31
Note The suggested values above are the values reserved by the Schematron specification. Only exslt, stx, xslt, xslt2, xslt3, xpath2, and xpath3 are defined by the specification. Most processors only support one or more of xslt, xslt2, and xslt3.

  - *@predeclare*

– *@module*

– att.combinable
* *@mode*

* att.deprecated
· *@validUntil*

• att.typed
– ~~type~~
– @subtype

`@type` characterizes the <constraintSpec> element in some sense; used to indicate when a <constraintSpec> warns about a deprecated construct.
Status Optional
Datatype teidata.enumerated
Suggested values include: **deprecationWarning** Indicates that this constraint specification warns that some other construct in the schema is deprecated.

`@scheme` supplies the name of the language in which the constraints are defined
Status Optional
Datatype teidata.enumerated
Schematron <sch:rule context="tei:constraintSpec[@mode = ('add','replace') or not(@mode)]"> <sch:assert test="@scheme"> The @scheme attribute of <constraintSpec> is required when the @mode is <sch:value-of select="if (@mode) then concat('"',@mode,'"') else 'not specified'"/> (here on "<sch:value-of select="@ident"/>").</sch:assert> </sch:rule>
Suggested values include: **schematron** (ISO Schematron)
Note These Guidelines no longer recommend, and the current TEI stylesheets no longer support, the use of Schematron 1.x within <constraintSpec>. Thus the value schematron is used to indicate that ISO Schematron is used within the <constraintSpec>.

The *scheme* attribute is required when the value of *mode* is add or replace. The *scheme* attribute is permitted when the value of *mode* is delete, but these Guidelines make no reccomendation for what a processor should do if its value does not match that of the <constraintSpec> being deleted.

Note A child <constraint> is required when the *mode* attribute has the value replace or add (or is not specified, as add is the default). No child elements are permitted when the *mode* attribute has the value delete. At least one child element is required when the *mode* attribute has the value change.

Example This constraint uses Schematron to enforce the presence of the *spanTo* attribute (which comes from an attribute class) on the <addSpan> element:

```
<constraintSpec ident="demo-c1"
  scheme="schematron"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>Enforce the presence of the <att>spanTo</att> attribute</desc>
  <constraint>
    <sch:rule context="tei:addSpan">
      <sch:assert test="@spanTo">The @spanTo attribute of <<sch:name/>> is
required.</sch:assert>
    </sch:rule>
  </constraint>
</constraintSpec>
```

Example

```
<constraintSpec ident="demo-c2"
  scheme="schematron"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>Implement an accessibility rule which says that pictures
     should have textual explanations</desc>
  <constraint>
    <sch:rule context="tei:figure">
      <sch:report test="not( tei:figDesc | tei:head )">You should
            provide information in a figure from which
            we can construct an @alt attribute in HTML.</sch:report>
    </sch:rule>
  </constraint>
</constraintSpec>
```

Example This constraint uses SPITBOL (a language which is not expressed in XML) to check whether the title and author are identical:

```
<constraintSpec ident="author_ne_title"
  scheme="SPITBOL">
  <constraint>
     (output = leq(title,author) "title and author cannot be the same")
  </constraint>
</constraintSpec>
```

Schematron <sch:rule context="tei:constraintSpec[@mode eq 'delete']"> <sch:report test="child::*">This

<constraintSpec> element has a @mode of ”delete” even though it has child elements. Change the @mode to ”add”, ”change”, or ”replace”, or remove the child elements.</sch:report> </sch:rule> <sch:rule context=”tei:constraintSpec[@mode eq ’change’]”> <sch:assert test=”child::*”>This <constraintSpec> element has a @mode of ”change”, but does not have any child elements. Specify child elements, or change the @mode to ”delete”.</sch:assert> </sch:rule> <sch:rule context=”tei:constraintSpec[@mode = (’add’,’replace’)]”> <sch:assert test=”child::tei:constraint”>This <constraintSpec> element has a @mode of ”<sch:value-of select=”@mode”/>”, but does not have a child ’constraint’ element. Use a child ’constraint’ element or change the @mode to ”delete” or ”change”.</sch:assert> </sch:rule>

Schematron Relationship between scheme attribute and contents: Schematron 1.x
<sch:rule context=”tei:constraintSpec”> <sch:report test=”tei:constraint/sch1x:* and @scheme = (’isoschematron’,’schematron’)”>Rules in the Schematron 1.* language must be inside a <constraintSpec> with a value other than ”schematron” or ”isoschematron” on the @scheme attribute.</sch:report> </sch:rule>

Schematron Relationship between scheme attribute and contents: ISO Schematron
<sch:rule context=”tei:constraintSpec[@mode = (’add’,’replace’) or not(@mode)]”> <sch:report test=”tei:constraint/sch:* and not(@scheme eq ’schematron’)”>Rules in the ISO Schematron language must be inside a <constraintSpec> with the value ”schematron” on the @scheme attribute.</sch:report> </sch:rule>

Schematron <sch:rule context=”(tei:constraintSpec|tei:constraintDecl)[@scheme eq ’schematron’][.//sch:assert | .//sch:report]”> <sch:let name=”assertsHaveContext” value=”for $a in .//sch:assert return exists($a/ancestor::sch:rule/@context)”/> <sch:let name=”reportsHaveContext” value=”for $r in .//sch:report return exists($r/ancestor::sch:rule/@context)”/> <sch:report test=”($assertsHaveContext, $reportsHaveContext) = false()”>An <sch:assert> or <sch:report> element must be a descendant of an <sch:rule> that has a @context; one or more inside this «sch:value-of select=”local-name(.)”/» are not.</sch:report> </sch:rule>

Schematron <sch:rule context=”tei:constraintSpec[@mode eq ’add’ or not(@mode)]”> <sch:let name=”myIdent” value=”normalize-space(@ident)”/> <sch:report test=”preceding::tei:constraintSpec[normalize-space(@ident) eq $myIdent]”> The @ident of <constraintSpec> should be unique; this one (<sch:value-of select=”$myIdent”/>) is the same as that of a previous <constraintSpec>. </sch:report> </sch:rule>

`@autoPrefix` controls whether or not pattern names generated in the corresponding RELAX NG schema source are automatically prefixed to avoid potential nameclashes.
Status Optional
Datatype teidata.truthValue
Legal values are: **true** Each name referenced in e.g. an `<rng:ref>` element within a content model is automatically prefixed by the value of the *prefix* attribute on the current <schemaSpec>[Default]
false No prefixes are added: any prefix required by the value of the *prefix* attribute on the current <schemaSpec> must therefore be supplied explicitly, as appropriate.

Contained by: *tei.declarables* dataSpec elementSpec macroSpec moduleRef
May contain ANY
Note It is required that the <content> element has only one child element. If several RELAX NG elements are desired, they must be wrapped in a `<rng:div>`.
Example This sample <content> element indicates that the element being specified has no content:

```
<content>
  <empty/>
</content>
```

Example This <content> element defines a content model, expressed directly in the TEI ODD language, that allows either a sequence of paragraphs or a series of <msItem> elements optionally preceded by a <summary>:

```
<content>
  <alternate>
    <classRef key="model.pLike"
      maxOccurs="unbounded"/>
    <sequence>
      <elementRef key="summary" minOccurs="0"
        maxOccurs="1"/>
      <elementRef key="msItem"
        maxOccurs="unbounded"/>
    </sequence>
  </alternate>
</content>
```

Example This sample <content> element defines a content model, expressed in the RELAX NG schema language, that allows either a sequence of paragraphs or a series of <msItem> elements optionally preceded by a <summary>:

```
<content>
  <rng:choice>
    <rng:oneOrMore>
      <rng:ref name="model.pLike"/>
    </rng:oneOrMore>
    <rng:group>
      <rng:optional>
        <rng:ref name="summary"/>
      </rng:optional>
      <rng:oneOrMore>
        <rng:ref name="msItem"/>
      </rng:oneOrMore>
    </rng:group>
```

```
      </rng:choice>
    </content>
```

Content model

```
<content>
 <alternate>
  <elementRef key="valList" minOccurs="1"
   maxOccurs="1"/>
  <classRef key="model.contentPart"
   minOccurs="1" maxOccurs="1"/>
  <anyElement minOccurs="1" maxOccurs="1"
   require="http://relaxng.org/ns/compatibility/annotations/1.0 http://relaxng.org/ns/stru
 </alternate>
</content>
```

Schema Declaration

```
element content
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,

– *@where*

`@fromUnit` indicates a source unit of measure that is to be converted into another unit indicated in *toUnit*.
Status Required
Datatype teidata.pointer

`@toUnit` the target unit of measurement for a conversion from a source unit referenced in *fromUnit*.
Status Required
Datatype teidata.pointer

Contained by: unitDef

May contain Empty element

Note The conversion element is designed to store information about converting from one unit of measurement to another. The *formula* attribute holds an XPath expression that indicates how the measurement system in *fromUnit* is converted to the system in *toUnit*. Do not confuse the usage of the dating attributes (*from* and *to*) in the examples with the attributes (*fromUnit* and *toUnit*) designed to reference units of measure.

Example

```
<conversion fromUnit="#shilling"
  toUnit="#pence" formula="$fromUnit * 12" from="1707"
  to="1971"/>
```

Example

```
<conversion fromUnit="#pound"
  toUnit="#shilling" formula="$fromUnit * 20" from="1701"
  to="1971"/>
```

Content model `<content> <empty/></content>`

Schema Declaration

character data

Example If all that is desired is to call attention to the fact that the copy text has been corrected, <corr> may be used alone:

```
I don't know,
Juan. It's so far in the past now — how <corr>can we</corr> prove
or disprove anyone's theories?
```

Example It is also possible, using the <choice> and <sic> elements, to provide an uncorrected reading:

```
I don't know, Juan. It's so far in the past now —
how <choice>
  <sic>we can</sic>
  <corr>can we</corr>
</choice> prove or
disprove anyone's theories?
```

`@status` indicates the degree of correction applied to the text.

Status Optional

Datatype teidata.enumerated

Legal values are: **high** the text has been thoroughly checked and proofread.

medium the text has been checked at least once.

low the text has not been checked.

unknown the correction status of the text is unknown.

`@method` indicates the method adopted to indicate corrections within the text.

Status Optional

Datatype teidata.enumerated

Legal values are: **silent** corrections have been made silently[Default]

markup corrections have been represented using markup

Member of model.editorialDeclPart

Contained by

header: editorialDecl

May contain

core: p

linking: ab

Note May be used to note the results of proof reading the text against its original, indicating (for example) whether discrepancies have been silently rectified, or recorded using the editorial tags described in section *3.5. Simple Editorial Changes*.

Example

```
<correction>
  <p>Errors in transcription controlled by using the WordPerfect spelling
checker, with a user
    defined dictionary of 500 extra words taken from Chambers Twentieth
Century
    Dictionary.</p>
</correction>
```

character data

Note The recommended source for codes to represent coded country names is ISO 3166.

Example

```
<country key="DK">Denmark</country>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element country
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,

character data

Note The <creation> element may be used to record details of a text's creation, e.g. the date and place it was composed, if these are of interest.

It may also contain a more structured account of the various stages or revisions associated with the evolution of a text; this should be encoded using the <listChange> element. It should not be confused with the <publicationStmt> element, which records date and place of publication.

Example

```
<creation>
  <date>Before 1987</date>
</creation>
```

Example

```
<creation>
  <date  when="1988-07-10">10 July 1988</date>
</creation>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.limitedPhrase"/>
  <elementRef key="listChange"/>
 </alternate>
</content>
```

Schema Declaration

```
element creation
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,

Note The result of the substitution may be either an absolute or a relative URI reference. In the latter case it is combined with the value of *xml:base* in force at the place where the *cRef* attribute occurs to form an absolute URI in the usual manner as prescribed by XML Base.
Example

```
<cRefPattern matchPattern="([1-9A-Za-z]+)\s+([0-9]+):([0-9]+)"
  replacementPattern="#xpath(//div[@type='book'][@n='$1']/div[@type='chap'][@n='$2']/div[@type

character data

Note Since damage to text witnesses frequently makes them harder to read, the <damage> element will often contain an <unclear> element. If the damaged area is not continuous (e.g. a stain affecting several strings of text), the *group* attribute may be used to group together several related <damage> elements; alternatively the <join> element may be used to indicate which <damage> and <unclear> elements are part of the same physical phenomenon.

The <damage>, <gap>, <del>, <unclear> and <supplied> elements may be closely allied in use. See section *12.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of which element is appropriate for which circumstance.

Example

```
<l>The Moving Finger wri<damage  agent="water"  group="1">es; and</damage>
having writ,</l>
<l>Moves <damage  agent="water"  group="1">
    <supplied>on: nor all your</supplied>
  </damage> Piety nor Wit</l>
```

Content model

```
<content>
 <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```
element damage
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.damaged.attributes,
```

```
   att.dimensions.attributes,
   att.ranging.attributes,
   att.written.attributes,
   att.typed.attributes,
   macro.paraContent}
```

<damageSpan>

(damaged span of text) marks the beginning of a longer sequence of text which is damaged in some way but still legible. [*12.3.3.1. Damage, Illegibility, and Supplied Text*]

May contain Empty element

Note Both the beginning and ending of the damaged sequence must be marked: the beginning by the <damageSpan> element, the ending by the target of the *spanTo* attribute: if no other element available, the <anchor> element may be used for this purpose.

The damaged text must be at least partially legible, in order for the encoder to be able to transcribe it. If it is not legible at all, the <damageSpan> element should not be used. Rather, the <gap> or <unclear> element should be employed, with the value of the *reason* attribute giving the cause. See further sections *12.3.3.1. Damage, Illegibility, and Supplied Text* and *12.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination.*

Example

```
<p>Paragraph partially damaged. This is the undamaged
portion <damageSpan  spanTo="#a34"/>and this the damaged
portion of the paragraph.</p>
<p>This paragraph is entirely damaged.</p>
<p>Paragraph partially damaged; in the middle of this
paragraph the damage ends and the anchor point marks
the start of the <anchor  xml:id="a34"/> undamaged part of the text. ...</p>
```

Schematron <sch:rule context="tei:damageSpan"> <sch:assert test="@spanTo">The @spanTo attribute of «sch:name/» is required.</sch:assert> </sch:rule>

Schematron <sch:rule context="tei:damageSpan"> <sch:assert test="@spanTo">L'attribut spanTo est requis.</sch:assert> </sch:rule>

Contained by: dataRef
May contain Empty element
Note This element is only allowed when the parent <dataRef> refers with *name* to a datatype from the specification XML Schema Part 2: Datatypes Second Edition.
Example

```
<datatype>
  <dataRef  name="decimal">
    <dataFacet  name="maxInclusive"
      value="360.0"/>
    <dataFacet  name="minInclusive"
      value="-360.0"/>
  </dataRef>
</datatype>
```

Example

```
<dataSpec  ident="data.integerExample">
  <desc>datatype used for attributes taking an integer value between 0 and
99</desc>
  <content>
    <dataRef  name="nonNegativeInteger">
      <dataFacet  name="maxInclusive"
        value="99"/>
      <dataFacet  name="minInclusive"  value="0"/>
    </dataRef>
  </content>
</dataSpec>
```

Content model `<content> <empty/></content>`
Schema Declaration

```
element dataFacet
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
```

```
   att.global.responsibility.attributes,
   att.global.source.attributes,
   attribute name
   {
      "length"
    | "minLength"
    | "maxLength"
    | "pattern"
    | "enumeration"
    | "whiteSpace"
    | "maxInclusive"
    | "minInclusive"
    | "maxExclusive"
    | "minExclusive"
    | "totalDigits"
    | "fractionDigits"
   },
   attribute value { text },
   empty
}
```

<dataRef> identifies the datatype of an attribute value, either by referencing an item in an externally defined datatype library, or by pointing to a TEI-defined data specification [*23.5.3.1. Datatypes*]

`@key` the identifier used for this datatype specification
Status Required
Datatype teidata.xmlName

`@name` the name of a datatype in the list provided by XML Schema Part 2: Datatypes Second Edition
Status Required
Datatype teidata.xmlName

`@ref` a pointer to a datatype defined in some datatype library
Status Required
Datatype teidata.pointer

`@restriction` supplies a string representing a regular expression providing additional constraints on the strings used to represent values of this datatype
Status Optional
Datatype teidata.pattern

Member of model.contentPart model.oddRef

Contained by

tagdocs: alternate content datatype interleave schemaSpec sequence specGrp

May contain

tagdocs: dataFacet

Note Only one of the attributes *key*, *name*, and *ref* may be used on any given instance of <dataRef>.

Neither a *restriction* attribute nor a <dataFacet> child element may be used unless the <dataRef> refers to a datatype from the specification XML Schema Part 2: Datatypes Second Edition with a *name* attribute.

Example

```
<schemaSpec ident="myTEI"
 source="http://www.tei-c.org/Vault/P5/current/xml/tei/odd/p5subset.xml">
<!-- ... -->
 <dataRef key="teidata.enumerated"/>
<!-- ... -->
</schemaSpec>
```

Example

```
<schemaSpec ident="myTEI"
 source="http://www.tei-c.org/Vault/P5/current/xml/tei/odd/p5subset.xml">
<!-- ... -->
 <dataRef name="float"/>
<!-- ... -->
</schemaSpec>
```

Example

```
<dataSpec ident="data.integerExample">
  <desc>datatype used for attributes taking an integer value between 0 and
99</desc>
  <content>
    <dataRef name="nonNegativeInteger"
      restriction="[0-9][0-9]?"/>
  </content>
</dataSpec>
```

Schematron <sch:rule context="tei:dataRef[tei:dataFacet]"> <sch:assert test="@name" role="nonfatal">Data facets can only be specified for references to datatypes specified by XML Schema Part 2: Datatypes Second Edition — that is, for there to be a <dataFacet> child there must be a @name attribute.</sch:assert> <sch:report test="@restriction" role="nonfatal">Data facets and restrictions cannot both be expressed on the same data reference — that is, the @restriction attribute cannot be used when a <dataFacet> child element is present.</sch:report> </sch:rule>

* *@source*

`@minOccurs` (minimum number of occurrences) indicates the minimum number of times this datatype may occur in an instance of the attribute being defined.
Derived from att.repeatable
Status Optional
Datatype teidata.count
Default 1

`@maxOccurs` (maximum number of occurrences) indicates the maximum number of times this datatype may occur in an instance of the attribute being defined.
Derived from att.repeatable
Status Optional
Datatype teidata.unboundedCount
Default 1

Contained by tagdocs: attDef
May contain ANY

Note In the TEI scheme, most datatypes are expressed using pre-defined TEI macros, which map a name in the form `teidata.xxxx` to a datatype defined by RELAX NG or the W3C Schema Language.

Example

```
<datatype>
  <dataRef name="token"/>
</datatype>
```

Example

```
<datatype>
  <dataRef key="teidata.enumerated"/>
</datatype>
```

Example The encoding in the following example requires that the attribute being defined contain at least two URIs in its value, as is the case for the *target* attribute of <join>.

```
<datatype  minOccurs="2"
  maxOccurs="unbounded">
  <dataRef  key="teidata.pointer"/>
</datatype>
```

Content model

```
<content>
 <alternate>
  <elementRef key="dataRef"/>
  <anyElement require="http://relaxng.org/ns/structure/1.0"/>
 </alternate>
</content>
```

Schema Declaration

```
element datatype
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   attribute minOccurs { text }?,
   attribute maxOccurs { text }?,
   ( dataRef | anyElement_datatype_6 )
}
```

character data

Example

```
<death  when="1902-10-01"/>
```

Example

```
<death  when="1960-12-10">Passed away near
<name  type="place">Aix-la-Chapelle</name>, after suffering from cerebral
palsy. </death>
```

Example

```
<death  when="2024-08-16"
  where="gn:US-NM-039-5467024"/>
```

In this example, the value of *where* demonstrates the use of private URI scheme and custom prefix (gn:), which would typically be defined by a <prefixDef> in the document's <teiHeader>.

character data

Note This element should be used for deletion of shorter sequences of text, typically single words or phrases. The <delSpan> element should be used for longer sequences of text, for those containing structural subdivisions, and for those containing overlapping additions and deletions.

The text deleted must be at least partially legible in order for the encoder to be able to transcribe it (unless it is restored in a <supplied> tag). Illegible or lost text within a deletion may be marked using the

<gap> tag to signal that text is present but has not been transcribed, or is no longer visible. Attributes on the <gap> element may be used to indicate how much text is omitted, the reason for omitting it, etc. If text is not fully legible, the <unclear> element (available when using the additional tagset for transcription of primary sources) should be used to signal the areas of text which cannot be read with confidence in a similar way.

Degrees of uncertainty over what can still be read, or whether a deletion was intended may be indicated by use of the <certainty> element (see *22. Certainty, Precision, and Responsibility*).

There is a clear distinction in the TEI between <del> and <surplus> on the one hand and <gap> or <unclear> on the other. <del> indicates a deletion present in the source being transcribed, which states the author's or a later scribe's intent to cancel or remove text. <surplus> indicates material present in the source being transcribed which should have been so deleted, but which is not in fact. <gap> or <unclear>, by contrast, signal an editor's or encoder's decision to omit something or their inability to read the source text. See sections *12.3.1.7. Text Omitted from or Supplied in the Transcription* and *12.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination* for the relationship between these and other related elements used in detailed transcription.

Example

```
<l>
  <del  rend="overtyped">Mein</del> Frisch
<del  rend="overstrike"  type="primary">schwebt</del>
weht der Wind
</l>
```

Example

```
<del  rend="overstrike">
  <gap  reason="illegible"  quantity="5"
    unit="character"/>
</del>
```

Content model

```
<content>
 <macroRef key="macro.paraContent"/>
</content>
```

May contain Empty element

Note Both the beginning and ending of the deleted sequence must be marked: the beginning by the <delSpan> element, the ending by the target of the *spanTo* attribute.

The text deleted must be at least partially legible, in order for the encoder to be able to transcribe it. If it is not legible at all, the <delSpan> tag should not be used. Rather, the <gap> tag should be employed to signal that text cannot be transcribed, with the value of the *reason* attribute giving the cause for the omission from the transcription as deletion. If it is not fully legible, the <unclear> element should be used to signal the areas of text which cannot be read with confidence. See further sections *12.3.1.7. Text Omitted from or Supplied in the Transcription* and, for the close association of the <delSpan> tag with the <gap>, <damage>, <unclear> and <supplied> elements, *12.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination.*

The <delSpan> tag should not be used for deletions made by editors or encoders. In these cases, either the <corr> tag or the <gap> tag should be used.

Example

```
<p>Paragraph partially deleted. This is the undeleted

character data

Note When used in a specification element such as <elementSpec>, TEI convention requires that this be expressed as a finite clause, begining with an active verb.

Example Example of a <desc> element inside a documentation element.

```
<dataSpec module="tei"
  ident="teidata.point">
  <desc versionDate="2010-10-17"
    xml:lang="en">defines the data type used to express a point in cartesian
space.</desc>
  <content>
    <dataRef name="token"
      restriction="(-?[0-9]+(\.[0-9]+)?,-?[0-9]+(\.[0-9]+)?)"/>
  </content>
<!-- ... -->
</dataSpec>
```

Example Example of a <desc> element in a non-documentation element.

```
<place xml:id="KERG2">
  <placeName>Kerguelen Islands</placeName>
<!-- ... -->
  <terrain>
    <desc>antarctic tundra</desc>
  </terrain>
<!-- ... -->
</place>
```

Schematron A <desc> with a *type* of deprecationInfo should only occur when its parent element is being deprecated. Furthermore, it should always occur in an element that is being deprecated when <desc> is a valid child of that element. <sch:rule context="tei:desc[@type eq 'deprecationInfo']"> <sch:assert test="../@validUntil">Information about a deprecation should only be present in a specification element that is being deprecated: that is, only an element that has a @validUntil attribute should have a child <desc type="deprecationInfo">.</sch:assert> </sch:rule>

character data

Note May contain any dictionary elements in any combination.

This element is used to mark part of a dictionary entry in which lower level dictionary elements appear, but which does not itself form an identifiable structural unit.

Example

```
<entry>
  <dictScrap>
    <orth>biryani</orth> or <orth>biriani</orth>
    <pron>(%bIrI"A:nI)</pron>
    <def>any of a variety of Indian dishes ...</def>
    <etym>[from <lang>Urdu</lang>]</etym>
  </dictScrap>
</entry>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
  <classRef key="model.entryPart"/>
  <classRef key="model.morphLike"/>
  <classRef key="model.phrase"/>
  <classRef key="model.inter"/>
  <classRef key="model.global"/>
 </alternate>
</content>
```

Schema Declaration

```
element dictScrap
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   (
      text
    | model.gLike    | model.entryPart    | model.morphLike    | model.phrase    | model.i
}
```

<dim> contains any single measurement forming part of a dimensional specification of some sort. [*11.3.4. Dimensions*]

• att.typed
– ~~type~~
– @subtype

`@type` indicates which aspect of the object is being measured.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Sample values include: **leaves** dimensions relate to one or more leaves (e.g. a single leaf, a gathering, or a separately bound part)
ruled dimensions relate to the area of a leaf which has been ruled in preparation for writing.
pricked dimensions relate to the area of a leaf which has been pricked out in preparation for ruling (used where this differs significantly from the ruled area, or where the ruling is not measurable).
written dimensions relate to the area of a leaf which has been written, with the height measured from the top of the minims on the top line of writing, to the bottom of the minims on the bottom line of writing.
miniatures dimensions relate to the miniatures within the manuscript
binding dimensions relate to the binding in which the codex or manuscript is contained
box dimensions relate to the box or other container in which the manuscript is stored.

tagdocs: eg valDesc

textcrit: lem rdg wit witDetail witness

textstructure: byline closer dateline docAuthor docDate docEdition docImprint imprimatur opener salute signed titlePart trailer

transcr: damage fw metamark mod restore retrace secl supplied surplus

verse: metSym rhyme

May contain

msdescription: depth dim height width

Note Contains no more than one of each of the specialized elements used to express a three-dimensional object's height, width, and depth, combined with any number of other kinds of dimensional specification.

Example

```
<dimensions type="leaves">
  <height scope="range">157-160</height>
  <width>105</width>
</dimensions>
<dimensions type="ruled">
  <height scope="most">90</height>
  <width scope="most">48</width>
</dimensions>
<dimensions unit="in">
  <height>12</height>
  <width>10</width>
</dimensions>
```

Example This element may be used to record the dimensions of any text-bearing object, not necessarily a codex. For example:

```
<dimensions type="panels">
  <height scope="all">7004</height>
  <width scope="all">1803</width>
  <dim type="relief" unit="mm">345</dim>
</dimensions>
```

This might be used to show that the inscribed panels on some (imaginary) monument are all the same size (7004 by 1803 cm) and stand out from the rest of the monument by 345 mm.

Example When simple numeric quantities are involved, they may be expressed on the *quantity* attribute of any or all of the child elements, as in the following example:

```
<dimensions type="leaves">

`@type` specifies the sublanguage or register to which the word or phrase is being assigned.
Derived from att.typed
Status Optional
Datatype teidata.enumerated

`@time` specifies how the phrase is distinct diachronically.
Status Optional
Datatype teidata.text

`@space` specifies how the phrase is distinct diatopically.
Status Optional
Datatype teidata.text

`@social` specifies how the phrase is distinct diastratically.
Status Optional
Datatype teidata.text

      <div5>
        <head>The apple</head>
        <p>This useful fruit is mentioned in Holy Writ; and Homer describes it
               as valuable in his time... As a food, the apple cannot be
considered
               to rank high, as more than the half of it consists of water, and
               the rest of its properties are not the most nourishing. It is
               however a useful adjunct to other kinds of food, and, when
cooked, is
               esteemed as slightly laxative.</p>
      </div5>

    * *@resp*
  - att.global.source
    * *@source*
- att.typed
  - ~~type~~
  - @subtype

`@type` specifies what type of generated text division (e.g. index, table of contents, etc.) is to appear.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Sample values include: **index** an index is to be generated and inserted at this point.

toc a table of contents

figlist a list of figures

tablist a table of tables

Note Valid values are application-dependent; those shown are of obvious utility in document production, but are by no means exhaustive.

Member of model.divGenLike model.frontPart

Contained by

textstructure: back body div div1 div2 div3 div4 div5 div6 front

May contain

core: head

Note This element is intended primarily for use in document production or manipulation, rather than in the transcription of pre-existing materials; it makes it easier to specify the location of indices, tables of contents, etc., to be generated by text preparation or word processing software.

Example One use for this element is to allow document preparation software to generate an index and insert it in the appropriate place in the output. The example below assumes that the *indexName* attribute on <index> elements in the text has been used to specify index entries for the two generated indexes, named NAMES and THINGS:

```
<back>
  <div1 type="backmat">
    <head>Bibliography</head>
<!-- ... -->
  </div1>
  <div1 type="backmat">
    <head>Indices</head>
    <divGen n="Index Nominum" type="NAMES"/>
```

```
      <divGen  n="Index Rerum"  type="THINGS"/>
    </div1>
  </back>
```

Example Another use for <divGen> is to specify the location of an automatically produced table of contents:

```
  <front>
  <!--<titlePage>...</titlePage>-->
    <divGen  type="toc"/>
    <div>
      <head>Preface</head>
      <p> ... </p>
    </div>
  </front>
```

Content model

```
<content>
 <classRef key="model.headLike"
  minOccurs="0" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element divGen
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.typed.attribute.subtype,
   attribute type { text }?,
   model.headLike*
}
```

<docAuthor>

<docAuthor> (document author) contains the name of the author of the document, as given on the title page (often but not always contained in a byline). [*4.6. Title Pages*]

character data

Note The document author's name often occurs within a byline, but the <docAuthor> element may be used whether the <byline> element is used or not. It should be used only for the author(s) of the entire document, not for author(s) of any subset or part of it. (Attributions of authorship of a subset or part of the document, for example of a chapter in a textbook or an article in a newspaper, may be encoded with <byline> without <docAuthor>.)

Example

```
<titlePage>
  <docTitle>
    <titlePart>Travels into Several Remote Nations of the World, in Four
        Parts.</titlePart>
  </docTitle>
  <byline> By <docAuthor>Lemuel Gulliver</docAuthor>, First a Surgeon,
     and then a Captain of several Ships</byline>
</titlePage>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element docAuthor
{
   att.global.attributes,
   att.global.analytic.attributes,

character data

Note Cf. the general <date> element in the core tag set. This specialized element is provided for convenience in marking and processing the date of the documents, since it is likely to require specialized handling for many applications. It should be used only for the date of the entire document, not for any subset or part of it.

Example

```
<docImprint>Oxford, Clarendon Press, <docDate>1987</docDate>
</docImprint>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element docDate
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.calendarSystem.attributes,
   att.cmc.attributes,
   att.datable.attributes,
   att.datable.custom.attributes,
   att.datable.iso.attributes,
   att.datable.w3c.attributes,
   macro.phraseSeq}
```

<docEdition> (document edition) contains an edition statement as presented on a title page of a document. [*4.6. Title Pages*]

character data

Note Cf. the <edition> element of bibliographic citation. As usual, the shorter name has been given to the more frequent element.

Example

```
<docEdition>The Third edition Corrected</docEdition>
```

Content model

```
<content>
 <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```
element docEdition
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   macro.paraContent}
```

<docImprint>

(document imprint) contains the imprint statement (place and date of publication, publisher name), as given (usually) at the foot of a title page. [*4.6. Title Pages*]

Module textstructure — Default Text Structure

verse: caesura rhyme

character data

Note Cf. the <imprint> element of bibliographic citations. As with title, author, and editions, the shorter name is reserved for the element likely to be used more often.

Example

```
<docImprint>Oxford, Clarendon Press, 1987</docImprint>
```

Imprints may be somewhat more complex:

```
<docImprint>
  <pubPlace>London</pubPlace>
Printed for <name>E. Nutt</name>,
at
<pubPlace>Royal Exchange</pubPlace>;
<name>J. Roberts</name> in
<pubPlace>wick-Lane</pubPlace>;
<name>A. Dodd</name> without
<pubPlace>Temple-Bar</pubPlace>;
and <name>J. Graves</name> in
<pubPlace>St. James's-street.</pubPlace>
  <date>1722.</date>
</docImprint>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
  <classRef key="model.phrase"/>
  <elementRef key="pubPlace"/>
  <elementRef key="docDate"/>
  <elementRef key="publisher"/>
  <classRef key="model.global"/>
 </alternate>
</content>
```

Schema Declaration

```
element docImprint
{
   att.global.attributes,
```

```
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   (
      text
    | model.gLike    | model.phrase    | pubPlace    | docDate    | publisher    | model.g
}
```

<docTitle>

(document title) contains the title of a document, including all its constituents, as given on a title page. [*4.6. Title Pages*]

character data

Note A consistent format should be adopted.

Particularly where cataloguing is likely to be based on the content of the header, it is advisable to use generally recognized authority lists for the exact form of personal names.

Example

```
<editor role="Technical_Editor">Ron Van den Branden</editor>
<editor role="Editor-in-Chief">John Walsh</editor>
<editor role="Managing_Editor">Anne Baillot</editor>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element editor
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.datable.attributes,
   att.datable.custom.attributes,
   att.datable.iso.attributes,
   att.datable.w3c.attributes,
   att.naming.attributes,
   att.canonical.attributes,
   macro.phraseSeq}
```

<editorialDecl>

<editorialDecl> (editorial practice declaration) provides details of editorial principles and practices applied during the encoding of a text. [*2.3.3. The Editorial Practices Declaration 2.3. The Encoding Description 16.3.2. Declarable Elements*]

character data

Note If the example contains material in XML markup, either it must be enclosed within a CDATA marked section, or character entity references must be used to represent the markup delimiters. If the example contains well-formed XML, it should be marked using the more specific <egXML> element.

Example

```
<p>The
<gi>term</gi> element is declared using the following syntax:
<eg><![CDATA[<!ELEMENT term (%phrase.content;)>]]</eg>
</p>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element eg
{
   att.global.attributes,
   att.global.analytic.attributes,
```

```
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   macro.phraseSeq}
```

<egXML> (example of XML) a single XML fragment demonstrating the use of some XML, such as elements, attributes, or processing instructions, etc., in which the <egXML> element functions as the root element. [*23.1.1. Phrase Level Terms*]

Namespace http://www.tei-c.org/ns/Examples

`@valid` indicates the intended validity of the example with respect to a schema.

Status Optional

Datatype teidata.enumerated

Legal values are: **true** the example is intended to be fully valid, assuming that its root element, or a provided root element, could have been used as a possible root element in the schema concerned.[Default]

feasible the example could be transformed into a valid document by inserting any number of valid attributes and child elements anywhere within it; or it is valid against a version of the schema concerned in which the provision of character data, list, element, or attribute values has been made optional.

false the example is not intended to be valid, and contains deliberate errors.

May contain ANY

Note In the source of the TEI Guidelines, this element declares itself and its content as belonging to the namespace `http://www.tei-c.org/ns/Examples`. This enables the content of the element to be validated independently against the TEI scheme. Where this element is used outside this context, a different namespace or none at all may be preferable. The content must however be a well-formed XML fragment or document: where this is not the case, the more general <eg> element should be used in preference.

Example

```
<egXML xmlns="http://www.tei-c.org/ns/Examples"><div>
   <head>A slide about <gi>egXML</gi>
   </head>
   <list>
     <item>
       <gi>egXML</gi> can be used to give XML examples in the TEI
           Examples namespace</item>
     <item>Attributes values for <att>valid</att>:
```

```
         <list  rend="collapsed">
            <item>
              <val  rend="green">true</val>: intended to be fully
                     valid</item>
            <item>
              <val  rend="amber">feasible</val>: valid if missing nodes
                     provided</item>
            <item>
              <val  rend="red">false</val>: not intended to be valid</item>
          </list>
         </item>
         <item>The <att>rend</att> attribute can be
               used for recording how parts of the example were rendered.</item>
      </list>
   </div>
   </egXML>
```

Example

```
   <egXML  valid="feasible"  source="#UND"
   xmlns="http://www.tei-c.org/ns/Examples"><text>
      <front>
   <!-- front matter for the whole group -->
      </front>
      <group>
        <text>
   <!-- first text -->
        </text>
        <text>
   <!-- second text -->
        </text>
      </group>
   </text>
   <!-- This example is not valid TEI, but could be made so by
   adding missing components -->
   </egXML>
```

Example

```
          <egXML xmlns="http://www.tei-c.org/ns/Examples" valid="false">
             <para xml:lang="en">Doubloons are a pirate's best friend</para>
          </egXML>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <anyElement/>
 </alternate>
</content>
```

Schema Declaration

```
element egXML
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,

`@value` indicates the value of an embedding leaf, which is a feature structure or other analytic element.
Status Optional
Datatype teidata.pointer

Contained by eTree triangle
May contain
core: label ptr ref
tagdocs: listRef
Note The <eTree> tag may be used if the encoder does not wish to distinguish by name between nonleaf and leaf nodes in embedding trees; they are distinguished by their arrangement.
Example

```
<eLeaf  value="http://an.fsurl.tei/#FSWITH">
  <label>with</label>
</eLeaf>
```

Content model

```
<content>
 <sequence>
  <elementRef key="label" minOccurs="0"/>
  <classRef key="model.ptrLike"
   minOccurs="0"/>
 </sequence>
</content>
```

Schema Declaration

```
element eLeaf
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.typed.attributes,
   attribute value { text }?,
   ( label?, model.ptrLike? )
}
```

<elementRef> points to the specification for some element which is to be included in a schema. [*23.2. Modules and Schemas*]

`@key` the identifier used for the required element within the source indicated.

Status Required

Datatype teidata.xmlName

Member of model.contentPart model.oddRef

Contained by

tagdocs: alternate content interleave schemaSpec sequence specGrp

May contain Empty element

Note Elements are identified by the name supplied as value for the *ident* attribute on the <elementSpec> element in which they are declared. TEI element names are unique.

Example

```
<elementRef key="p"/>
```

Include in the schema an element named <p> available from the current default source.

Example

```
<elementRef key="p" source="tei:1.2.1"/>
```

Include in the schema an element named <p> available from the TEI P5 1.2.1 release.

Schematron <sch:pattern> <sch:rule context="tei:elementRef[parent::tei:schemaSpec | parent::tei:specGrp]"> <sch:report test="@minOccurs | @maxOccurs" role="error">An element reference is not repeatable when part of a schema specification (and thus this <elementRef> should not have @minOccurs or @maxOccurs).</sch:report> </sch:rule> <sch:rule context="tei:content//tei:elementRef"> <sch:report test="@source" role="error">An element reference within a content model must refer to a locally defined element specification (and thus this <elementRef> should not have @source).</sch:report> </sch:rule> </sch:pattern>

Content model `<content> <empty/></content>`

Schema Declaration

Note Unlike <gap>, which indicates content that the encoder cannot or chooses not to represent, <ellipsis> indicates a passage explicitly signalled in the source document as absent. The <ellipsis> element is not appropriate for every use of ellipsis points, such as when they indicate that a speaker is pausing.

Example

```
<lg>
  <l>What projects men make—what queer turns they take,</l>
  <l>Since <emph>steam</emph> has improved our condition;</l>
  <l>They never are still, but must cure or must kill</l>
  <l>With steam physic or steam ammunition.</l>
  <l>But a short time ago, to a quack you would go,</l>
  <l>To steam a fat man to a thinner;</l>
  <l>Now changed from all that, if you wish to get <emph>fat</emph>,</l>
  <l>Come to Barton’s and eat a <emph>steam dinner!</emph>
  </l>
  <l>Oh dear! think of a scheme, odd though it seem—</l>
  <l>I’m sure ’twill succeed if you make it by steam.</l>
</lg>
<lg>
  <l>You may sleep, you may dream, you may travel by steam,</l>
  <l>For the outcry is still to go faster;</l>
  <l>And what does it reck, should you e’en break your neck,</l>
  <l>If ’tis <emph>steam</emph> that brings on the disaster?</l>
  <ellipsis  resp="#ChambersEdnbrghJrnl1880">
    <metamark  function="multilineEllipsis"> * * * * </metamark>
    <desc  resp="#teiProjectEditor2021">The printer omits four lines here,
        skipping the second half of the second octave, before the
refrain.</desc>
  </ellipsis>
  <l>Oh dear! think of a scheme, odd though it seem—</l>
  <l>I’m sure ’twill succeed if you make it by steam.</l>
</lg>
```

Example

```
<lg>
  <l>You think you’ve lost your love </l>
  <l>Well, I saw her yesterday </l>
  <l>It’s you she's thinking of </l>
  <l>And she told me what to say</l>
</lg>
<lg  xml:id="chorus">
  <label>[Refrain]</label>
  <l>She says she loves you </l>
```

```
      <l>And you know that can't be bad </l>
      <l>Yes, she loves you </l>
      <l>And you know you should be glad</l>
    </lg>
    <lg>
      <l>She said you hurt her so </l>
      <l>She almost lost her mind </l>
      <l>But now she said she knows </l>
      <l>You're not the hurting kind</l>
    </lg>
    <ellipsis>
      <metamark>******</metamark>
      <supplied  copyOf="#chorus"/>
    </ellipsis>
```

Content model

transcr: addSpan damageSpan delSpan fw listTranspose metamark space substJoin

Note Like all elements, <entry> inherits an *xml:id* attribute from the class *global*. No restrictions are placed on the method used to construct *xml:id*s; one convenient method is to use the orthographic form of the headword, appending a disambiguating number where necessary. Identification codes are sometimes included on machine-readable tapes of dictionaries for in-house use.

It is recommended to use the <sense> element even for an entry that has only one sense to group together all parts of the definition relating to the word sense since this leads to more consistent encoding across entries.

Example

```
<entry>
  <form>
    <orth>disproof</orth>
    <pron>dIs"pru:f</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <sense  n="1">
    <def>facts that disprove something.</def>
  </sense>
```

```
    <sense  n="2">
      <def>the act of disproving.</def>
    </sense>
  </entry>
```

Content model

```
<content>
 <alternate minOccurs="1"
  maxOccurs="unbounded">
  <elementRef key="hom"/>
  <elementRef key="sense"/>
  <elementRef key="pc"/>
  <classRef key="model.entryPart.top"/>
  <classRef key="model.global"/>
  <classRef key="model.ptrLike"/>
 </alternate>
</content>
```

Schema Declaration

`@name` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), naming the underlying concept of which the parent is a representation.
Status Optional
Datatype teidata.name

`@uri` (uniform resource identifier) references the underlying concept of which the parent is a representation by means of some external identifier.
Status Optional
Datatype teidata.pointer

`@filter` references an external script which contains a method to transform instances of this element to canonical TEI.
Status Optional
Datatype teidata.pointer

Member of model.identEquiv

tagdocs: attDef classSpec constraintDecl constraintSpec dataSpec elementSpec macroSpec model modelGrp modelSequence moduleSpec paramSpec schemaSpec valItem

May contain Empty element

Note The *mimeType* attribute should be used to supply the MIME media type of the filter script specified by the *filter* attribute.

Example The following example declares that the `<bo>` element is conceptually equivalent to the markup construct <hi rend='bold'>, and that an external definition of this concept is available from the URI indicated

```
<elementSpec ident="hi" mode="change">
  <equiv name="BOLD"/>
  <desc>bold typography</desc>
  <attList>
    <attDef ident="rend" mode="change">
      <valList>
        <valItem ident="bold"/>
      </valList>
    </attDef>
  </attList>
</elementSpec>
<elementSpec ident="bo" mode="add">
  <equiv name="BOLD"
    uri="http://www.example.com/typesetting/bold"/>
</elementSpec>
```

Content model `<content> <empty/></content>`

character data

Note May contain character data mixed with any other elements defined in the dictionary tag set.

There is no consensus on the internal structure of etymologies, or even on whether such a structure is appropriate. The <etym> element accordingly simply contains prose, within which names of languages, cited words, or parts of words, glosses, and examples will typically be prominent. The tagging of such internal objects is optional.

Example

```
<entry>
  <form>
    <orth>publish</orth> ... </form>
  <etym>
    <lang>ME.</lang>
    <mentioned>publisshen</mentioned>,
  <lang>F.</lang>
    <mentioned>publier</mentioned>, <lang>L.</lang>
    <mentioned>publicare,
        publicatum</mentioned>. <xr>See <ref>public</ref>; cf. 2d
```

```
    <ref>-ish</ref>.</xr>
      </etym>
    </entry> (From: Webster's Second International)
```

Example

```
    <entry>
      <form>
        <orth>Handschuh</orth> ... </form>
      <etym  type="compounding">
        <oRef>Hand</oRef> (<pRef  notation="ipa">'hant</pRef>): <gloss>hand</gloss>,
      <etym  type="metaphor">
          <oRef>Schuh</oRef> (<pRef  notation="ipa">ʃuː</pRef>): <gloss>shoe</gloss>
        </etym>
      </etym>
    </entry>
```

character data

Note The content of this element should be the expanded abbreviation, usually (but not always) a complete word or phrase. The <ex> element provided by the `transcr` module may be used to mark up sequences of letters supplied within such an expansion.

If abbreviations are expanded silently, this practice should be documented in the <editorialDecl>, either with a <normalization> element or a <p>.

Example

```
The address is Southmoor
<choice>
  <expan>Road</expan>
  <abbr>Rd</abbr>
</choice>
```

Example

```
<choice  xml:lang="la">
  <abbr>Imp</abbr>
  <expan>Imp<ex>erator</ex>
  </expan>
</choice>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element expan
{

`@name` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), providing a name for the feature.

Status Required

Datatype teidata.name

`@fVal` (feature value) references any element which can be used to represent the value of a feature.

Status Optional

Datatype teidata.pointer

Note If this attribute is supplied as well as content, the value referenced is to be unified with that contained.

Contained by iso-fs: bicond cond fLib fs if

May contain

iso-fs: binary default fs numeric string symbol vAlt vColl vLabel vMerge vNot

character data

Note The content of <f> may be textual, with the assumption that the data type of the feature value is determined by the schema—this is the approach used in many language-technology-oriented projects and recommendations.

Example

```
<f  name="gender">
  <symbol  value="feminine"/>
</f>
```

Example

```
<fs>
  <f  name="voice">active</f>
  <f  name="tense">SimPre</f>
</fs>
```

Content model

character data
Note Usually empty, unless some further clarification of the type attribute is needed, in which case it may contain running prose

For many literary texts, a simple binary opposition between 'fiction' and 'fact' is naïve in the extreme; this parameter is not intended for purposes of subtle literary analysis, but as a simple means of characterizing the claimed fictiveness of a given text. No claim is made that works characterized as 'fact' are in any sense 'true'.

Example

```
<factuality type="fiction"/>
```

Example

```
<factuality  type="mixed">contains a mixture of gossip and
speculation about real people and events</factuality>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq.limited"/>

`@name` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), indicating the name of the feature being declared; matches the *name* attribute of <f> elements in the text.
Status Required
Datatype teidata.name

`@optional` indicates whether or not the value of this feature may be present.
Status Optional
Datatype teidata.truthValue
Default true
Note If a feature is marked as optional, it is possible for it to be omitted from a feature structure. If an obligatory feature is omitted, then it is understood to have a default value, either explicitly declared, or, if no default is supplied, the special value any. If an optional feature is omitted, then it is understood to be missing and any possible value (including the default) is ignored.

Contained by: *iso-fs:* fsDecl
May contain

character data

Note This element is intended for use as an alternative to the content of its parent <figure> element ; for example, to display when the image is required but the equipment in use cannot display graphic images. It may also be used for indexing or documentary purposes.

Example

```
<figure>
  <graphic  url="emblem1.png"/>
  <head>Emblemi d'Amore</head>
  <figDesc>A pair of naked winged cupids, each holding a
     flaming torch, in a rural setting.</figDesc>
</figure>

May contain

header: editionStmt extent notesStmt publicationStmt seriesStmt sourceDesc titleStmt

Note The major source of information for those seeking to create a catalogue entry or bibliographic citation for an electronic file. As such, it provides a title and statements of responsibility together with details of the publication or distribution of the file, of any series to which it belongs, and detailed bibliographic notes for matters not addressed elsewhere in the header. It also contains a full bibliographic description for the source or sources from which the electronic text was derived.

Example

```
<fileDesc>
  <titleStmt>
    <title>The shortest possible TEI document</title>
  </titleStmt>
  <publicationStmt>
    <p>Distributed as part of TEI P5</p>
  </publicationStmt>
  <sourceDesc>
    <p>No print source exists: this is an original digital text</p>

  <msIdentifier>
    <settlement>Faraway</settlement>
  </msIdentifier>
<!-- ... -->
</msDesc>
```

In this example, the reference to 'Dujchev N17' includes a link to some other manuscript description which has the identifier DN17.

Example

```
<msItem>
  <title>Guan-ben</title>
  <filiation>
    <p>The "Guan-ben" was widely current among mathematicians in the
        Qing dynasty, and "Zhao Qimei version" was also read. It is
        therefore difficult to know the correct filiation path to follow.
        The study of this era is much indebted to Li Di. We explain the
        outline of his conclusion here. Kong Guangsen
        (1752-1786)(17) was from the same town as Dai Zhen, so he obtained
        "Guan-ben" from him and studied it(18). Li Huang (d. 1811)
        (19) took part in editing Si Ku Quan Shu, so he must have had
        "Guan-ben". Then Zhang Dunren (1754-1834) obtained this version,
        and studied "Da Yan Zong Shu Shu" (The General Dayan
        Computation). He wrote Jiu Yi Suan Shu (Mathematics
        Searching for One, 1803) based on this version of Shu Xue Jiu
        Zhang (20).</p>
    <p>One of the most important persons in restoring our knowledge
        concerning the filiation of these books was Li Rui (1768(21)
        -1817)(see his biography). ... only two volumes remain of this
        manuscript, as far as chapter 6 (chapter 3 part 2) p.13, that is,
        question 2 of "Huan Tian San Ji" (square of three loops),
        which later has been lost.</p>
  </filiation>
</msItem>

Note A floating text has the same content as any other <text> and may thus be interrupted by another floating text, or contain a <group> of tesselated texts.

Example

```
<body>
  <div  type="scene">
    <sp>
      <p>Hush, the players begin...</p>
    </sp>
    <floatingText  type="pwp">
      <body>
        <div  type="act">
          <sp>
            <l>In Athens our tale takes place [...]</l>
          </sp>
<!-- ... rest of nested act here -->
        </div>
      </body>
    </floatingText>
    <sp>
      <p>Now that the play is finished ...</p>
    </sp>
  </div>
</body>
```

Content model

```
<content>
 <sequence>
  <classRef key="model.global"
   minOccurs="0" maxOccurs="unbounded"/>
  <sequence minOccurs="0">
   <elementRef key="front"/>

character data

Note The global *xml:lang* attribute should be supplied for this element to identify the language of the word or phrase marked. As elsewhere, its value should be a language tag as defined in *vi.1 Language Identification*.

This element is intended for use only where no other element is available to mark the phrase or words concerned. The global *xml:lang* attribute should be used in preference to this element where it is intended to mark the language of the whole of some text element.

The <distinct> element may be used to identify phrases belonging to sublanguages or registers not generally regarded as true languages.

Example

```
This is
heathen Greek to you still? Your <foreign  xml:lang="la">lapis
philosophicus</foreign>?
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
```

Derived from att.typed
Status Optional
Datatype teidata.enumerated
Suggested values include: **simple** single free lexical item
lemma the headword itself
variant a variant form
compound word formed from simple lexical items
derivative word derived from headword
inflected word in other than usual dictionary form
phrase multiple-word lexical item

</front>
```

Example

```
<front>
  <div  type="dedication">
    <p>To our three selves</p>
  </div>
  <div  type="preface">
    <head>Author's Note</head>
    <p>All the characters in this book are purely imaginary, and if the
        author has used names that may suggest a reference to living persons
        she has done so inadvertently. ...</p>
  </div>
</front>
```

Example

```
<front>
  <div  type="abstract">
    <div>
      <head> BACKGROUND:</head>
      <p>Food insecurity can put children at greater risk of obesity because
            of altered food choices and nonuniform consumption patterns.</p>
    </div>
    <div>
      <head> OBJECTIVE:</head>
      <p>We examined the association between obesity and both child-level
            food insecurity and personal food insecurity in US children.</p>
    </div>
    <div>
      <head> DESIGN:</head>
      <p>Data from 9,701 participants in the National Health and Nutrition
            Examination Survey, 2001-2010, aged 2 to 11 years were analyzed.
            Child-level food insecurity was assessed with the US Department of
            Agriculture's Food Security Survey Module based on eight
            child-specific questions. Personal food insecurity was assessed with
            five additional questions. Obesity was defined, using physical
            measurements, as body mass index (calculated as kg/m2) greater than
            or equal to the age- and sex-specific 95th percentile of the Centers
            for Disease Control and Prevention growth charts. Logistic
            regressions adjusted for sex, race/ethnic group, poverty level, and
            survey year were conducted to describe associations between obesity
            and food insecurity.</p>
    </div>
    <div>
      <head> RESULTS:</head>
      <p>Obesity was significantly associated with personal food insecurity
            for children aged 6 to 11 years (odds ratio=1.81; 95% CI 1.33 to
            2.48), but not in children aged 2 to 5 years (odds ratio=0.88; 95%
            CI 0.51 to 1.51). Child-level food insecurity was not associated
            with obesity among 2- to 5-year-olds or 6- to 11-year-olds.</p>
    </div>
    <div>
      <head> CONCLUSIONS:</head>
      <p>Personal food insecurity is associated with an increased risk of
            obesity only in children aged 6 to 11 years. Personal
            food-insecurity measures may give different results than aggregate
            food-insecurity measures in children.</p>
    </div>
```

```
    </div>
  </front>

`@type` specifies the type of the feature structure.
Status Optional
Datatype teidata.enumerated

`@feats` (features) references the feature-value specifications making up this feature structure.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace
Note May be used either instead of having features as content, or in addition. In the latter case, the features referenced and contained are unified.

`@type` gives a name for the type of feature structure being declared.
Status Required
Datatype teidata.enumerated

`@baseTypes` gives the name of one or more typed feature structures from which this type inherits feature specifications and constraints; if this type includes a feature specification with the same name as that of any of those specified by this attribute, or if more than one specification of the same name is inherited, then the set of possible values is defined by unification. Similarly, the set of constraints applicable is derived by combining those specified explicitly within this element with those implied by the *baseTypes* attribute. When no *baseTypes* attribute is specified, no feature specification or constraint is inherited.
Status Optional
Datatype 1–∞ occurrences of teidata.name separated by whitespace
Note Inheritance is defined here as a monotonous relation.

The process of combining constraints may result in a contradiction, for example if two specifications for the same feature specify disjoint ranges of values, and at least one such specification is mandatory. In such a case, there is no valid representative for the type being defined.

character data

Note Where running heads are consistent throughout a chapter or section, it is usually more convenient to relate them to the chapter or section, e.g. by use of the *rend* attribute. The <fw> element is intended for cases where the running head changes from page to page, or where details of page layout and the internal structure of the running heads are of paramount importance.

Example

```
<fw type="sig" place="bottom">C3</fw>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element fw
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
```

```
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.placement.attributes,
   att.written.attributes,
   att.typed.attribute.subtype,
   attribute type { text }?,
   macro.phraseSeq}
```

<g> (character or glyph) represents a glyph, or a non-standard character. [*5. Characters, Glyphs, and Writing Modes*]

Module gaiji — Characters, Glyphs, and Writing Modes

May contain Character data only
Note The name `g` is short for *gaiji*, which is the Japanese term for a non-standardized character or glyph.
Example

```
<g ref="#ctlig">ct</g>
```

This example points to a <glyph> element with the identifier `ctlig` like the following:

```
<glyph xml:id="ctlig">
<!-- here we describe the particular ct-ligature intended -->
</glyph>
```

Example

```
<g  ref="#per-glyph">per</g>
```

The medieval brevigraph per could similarly be considered as an individual glyph, defined in a <glyph> element with the identifier `per-glyph` as follows:

```
<glyph  xml:id="per-glyph">
<!-- ... -->
</glyph>
```

Content model `<content> <textNode/></content>`

Schema Declaration

```

`@reason` (reason) gives the reason for omission.

Status Optional

Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace

Suggested values include: **cancelled** (cancelled)
deleted (deleted)
editorial (editorial) for features omitted from transcription due to editorial policy
illegible (illegible)
inaudible (inaudible)
irrelevant (irrelevant)
sampling (sampling)

`@agent` (agent) in the case of text omitted because of damage, categorizes the cause of the damage, if it can be identified.
Status Optional
Datatype teidata.enumerated
Sample values include: **rubbing** (rubbing) damage results from rubbing of the leaf edges
mildew (mildew) damage results from mildew on the leaf surface
smoke (smoke) damage results from smoke

core: desc

Note The <gap>, <unclear>, and <del> core tag elements may be closely allied in use with the <damage> and <supplied> elements, available when using the additional tagset for transcription of primary sources. See section *12.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of which element is appropriate for which circumstance.

The <gap> tag simply signals the editors decision to omit or inability to transcribe a span of text. Other information, such as the interpretation that text was deliberately erased or covered, should be indicated using the relevant tags, such as <del> in the case of deliberate deletion.

Example

```
<gap quantity="4" unit="chars"
 reason="illegible"/>
```

Example

```
<gap quantity="1" unit="essay"
 reason="sampling"/>
```

Example

```
<del>
 <gap atLeast="4" atMost="8" unit="chars"
  reason="illegible"/>
</del>
```

Example

```
<gap extent="several lines" reason="lost"/>
```

Content model

```

May contain Empty element

Note By convention, <gb> elements should appear at the start of the first page in the gathering. The global *n* attribute indicates the number or other value used to identify this gathering in a collation.

The *type* attribute may be used to further characterize the gathering in any respect.

Example

```
<gb  n="iii"/>
<pb  n="2r"/>
<!-- material from page 2 recto of gathering iii here -->
<pb  n="2v"/>
<!-- material from page 2 verso of gathering iii here -->
```

Content model `<content> <empty/></content>`

character data

Note As with other culturally-constructed traits such as age and sex, the way in which this concept is described in different cultural contexts varies. The normalizing attributes are provided only as an optional means of simplifying that variety for purposes of interoperability or project-internal taxonomies for consistency, and should not be used where that is inappropriate or unhelpful. The content of the element may be used to describe the intended concept in more detail.

Example

```
<gender value="W">woman</gender>
```

Example

```
<gender value="NB">non-binary</gender>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>

May contain Character data only

Note Uses of <geo> can be associated with a coordinate system, defined by a <geoDecl> element supplied in the TEI header, using the *decls* attribute. If no such link is made, the assumption is that the content of each <geo> element will be a pair of numbers separated by whitespace, to be interpreted as latitude followed by longitude according to the World Geodetic System.

Example

```
<geoDecl xml:id="WGS" datum="WGS84">World Geodetic System</geoDecl>
<geoDecl xml:id="OS" datum="OSGB36">Ordnance Survey</geoDecl>
```

```
<!-- ... -->
<location>
  <desc>A tombstone plus six lines of
     Anglo-Saxon text, built into the west tower (on the south side
     of the archway, at 8 ft. above the ground) of the
     Church of St. Mary-le-Wigford in Lincoln.</desc>
  <geo  decls="#WGS">53.226658 -0.541254</geo>
  <geo  decls="#OS">SK 97481 70947</geo>
</location>
```

Example

```
<geo>41.687142 -74.870109</geo>
```

Content model <content> <textNode/></content>

Schema Declaration

```
element geo
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.cmc.attributes,
   att.declaring.attributes,
   text
}
```

<geoDecl>

(geographic coordinates declaration) documents the notation and the datum used for geographic coordinates expressed as content of the <geo> element elsewhere within the document. [*2.3.8. The Geographic Coordinates Declaration*]

Module header — The TEI Header

`@datum` supplies a commonly used code name for the datum employed.

Status Optional

Datatype teidata.enumerated

Suggested values include: **WGS84** (World Geodetic System) a pair of numbers to be interpreted as latitude followed by longitude according to the World Geodetic System.[Default]

MGRS (Military Grid Reference System) values supplied follow the Military Grid Reference System, which designates grid zones in a string of letters and numbers that distinctly indicate each square meter on the planet.

OSGB36 (ordnance survey great britain) the value supplied is to be interpreted as a British National Grid Reference.

ED50 (European Datum coordinate system) the value supplied is to be interpreted as latitude followed by longitude according to the European Datum coordinate system.

May contain XSD Name

Example

```
<p>The <gi>xhtml:li</gi> element is roughly analogous to the <gi>item</gi>
element, as is the
<gi  scheme="DBK">listItem</gi> element.</p>
```

This example shows the use of both a namespace prefix and the *scheme* attribute as alternative ways of indicating that the <gi> in question is not a TEI element name: in practice only one method should be adopted.

- att.typed
  - ~~type~~
  - @subtype

`@type` classifies grammatical information provided by <gram> according to some convenient and shared typology, ideally one defined in an external reference taxonomy, such as the CLARIN Concept Registry.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Sample values include: **pos** (part of speech) any of the word classes to which a word may be assigned in a given language, based on form, meaning, or a combination of features, e.g. noun, verb, adjective, etc.
gen (gender) formal classification by which nouns and pronouns, and often accompanying modifiers, are grouped and inflected, or changed in form, so as to control certain syntactic relationships
num (number) grammatical number, e.g. singular, plural, dual, …
animate animate or inanimate
proper proper noun or common noun
Note The list of values for the *type* attribute should best come from a standardized set of container data categories.

  - att.global.responsibility
    * *@cert*
    * *@resp*
  - att.global.source
    * *@source*
- att.typed
  - ~~type~~
  - @subtype

`@type` describes the type of graph.

Derived from att.typed

Status Recommended

Datatype teidata.enumerated

Suggested values include: **undirected** undirected graph

directed directed graph

transitionNetwork a directed graph with distinguished initial and final nodes

transducer a transition network with up to two labels on each arc

Note If *type* is specified as undirected, then the distinction between the *to* and *from* attributes of the <arc> tag is neutralized. Also, the *adj* attribute, rather than the *adjFrom* and *adjTo* attributes, should be used to encode pointers to the ends of the arcs. If *type* is specified as directed (or any other value which implies directionality), then the *adjFrom* and *adjTo* attributes should be used, instead of the *adj* attribute.

`@order` states the order of the graph, i.e., the number of its nodes.

Status Optional

Datatype teidata.count

`@size` states the size of the graph, i.e., the number of its arcs.

Status Optional
Datatype teidata.count

Note The *mimeType* attribute should be used to supply the MIME media type of the image specified by the *url* attribute.

Within the body of a text, a <graphic> element indicates the presence of a graphic component in the source itself. Within the context of a <facsimile> or <sourceDoc> element, however, a <graphic> element provides an additional digital representation of some part of the source being encoded.

Example

```
<figure>
  <graphic  url="fig1.png"/>
  <head>Figure One: The View from the Bridge</head>
  <figDesc>A Whistleresque view showing four or five sailing boats in the
foreground, and a
    series of buoys strung out between them.</figDesc>
</figure>
```

Example

```
<facsimile>
  <surfaceGrp  n="leaf1">
    <surface>
      <graphic  url="page1.png"/>
    </surface>
    <surface>
      <graphic  url="page2-highRes.png"/>
      <graphic  url="page2-lowRes.png"/>
    </surface>
  </surfaceGrp>
</facsimile>
```

Example

May contain Empty element

Note The <handShift> element may be used either to denote a shift in the document hand (as from one scribe to another, on one writing style to another). Or, it may indicate a shift within a document hand, as a change of writing style, character or ink. Like other milestone elements, it should appear at the point of transition from some other state to the state which it describes.

Example

```
<l>When wolde the cat dwelle in his ynne</l>
<handShift  medium="greenish-ink"/>
<l>And if the cattes skynne be slyk <handShift  medium="black-ink"/> and
gaye</l>
```

Content model `<content> <empty/></content>`

Schema Declaration

```

character data

Note The <head> element is used for headings at all levels; software which treats (e.g.) chapter headings, section headings, and list titles differently must determine the proper processing of a <head> element based on its structural position. A <head> occurring as the first element of a list is the title of that list; one occurring as the first element of a <div1> is the title of that chapter or section.

Example The most common use for the <head> element is to mark the headings of sections. In older writings, the headings or *incipits* may be rather longer than usual in modern works. If a section has an explicit ending as well as a heading, it should be marked as a <trailer>, as in this example:

```
<div1 n="I" type="book">
  <head>In the name of Christ here begins the first book of the ecclesiastical
history of
    Georgius Florentinus, known as Gregory, Bishop of Tours.</head>
  <div2 type="section">
    <head>In the name of Christ here begins Book I of the history.</head>
    <p>Proposing as I do ...</p>
    <p>From the Passion of our Lord until the death of Saint Martin four
hundred and twelve
        years passed.</p>
    <trailer>Here ends the first Book, which covers five thousand, five hundred
and ninety-six
        years from the beginning of the world down to the death of Saint
Martin.</trailer>
  </div2>
</div1>
```

Example When headings are not inline with the running text (see e.g. the heading ”Secunda conclusio”) they might however be encoded as if. The actual placement in the source document can be captured with the *place* attribute.

```
<div type="subsection">
  <head place="margin">Secunda conclusio</head>
  <p>
    <lb n="1251"/>
    <hi rend="large">Potencia: habitus: et actus: recipiunt speciem ab
obiectis<supplied>.</supplied>
    </hi>
    <lb n="1252"/>Probatur sic. Omne importans necessariam habitudinem ad
proprium
```

```
      [...]
    </p>
  </div>
```

Example The <head> element is also used to mark headings of other units, such as lists:

```
With a few exceptions, connectives are equally
useful in all kinds of discourse: description, narration, exposition, argument.
<list  rend="bulleted">
  <head>Connectives</head>
  <item>above</item>
  <item>accordingly</item>
  <item>across from</item>
  <item>adjacent to</item>
  <item>again</item>
  <item>
<!-- ... -->
  </item>
</list>
```

Content model

- att.declarable
  - *@default*

`@eol` (end-of-line) indicates whether or not end-of-line hyphenation has been retained in a text.

Status Optional

Datatype teidata.enumerated

Legal values are: **all** all end-of-line hyphenation has been retained, even though the lineation of the original may not have been.

some end-of-line hyphenation has been retained in some cases.[Default]

hard all soft end-of-line hyphenation has been removed: any remaining end-of-line hyphenation should be retained.

none all end-of-line hyphenation has been removed: any remaining hyphenation occurred within the line.

`@type` categorizes the identifier, for example as an ISBN, Social Security number, etc.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: **ISBN** International Standard Book Number: a 13- or (if assigned prior to 2007) 10-digit identifying number assigned by the publishing industry to a published book or similar item, registered with the International ISBN Agency.

ISSN International Standard Serial Number: an eight-digit number to uniquely identify a serial publication.

DOI Digital Object Identifier: a unique string of letters and numbers assigned to an electronic document.

URI Uniform Resource Identifier: a string of characters to uniquely identify a resource, following the syntax of RFC 3986.

VIAF A data number in the Virtual Internet Authority File assigned to link different names in catalogs around the world for the same entity.

ESTC English Short-Title Catalogue number: an identifying number assigned to a document in English printed in the British Isles or North America before 1801.

OCLC OCLC control number (record number) for the union catalog record in WorldCat, a union catalog for member libraries in the Online Computer Library Center global cooperative.

gaiji: g

header: idno

character data

Note <idno> should be used for labels which identify an object or concept in a formal cataloguing system such as a database or an RDF store, or in a distributed system such as the World Wide Web. Some suggested values for *type* on <idno> are ISBN, ISSN, DOI, and URI.

Example

```
<idno type="ISBN">978-1-906964-22-1</idno>
<idno type="ISSN">0143-3385</idno>
<idno type="DOI">10.1000/123</idno>
<idno type="URI">http://www.worldcat.org/oclc/185922478</idno>
<idno type="URI">http://authority.nzetc.org/463/</idno>
<idno type="LT">Thomason Tract E.537(17)</idno>
<idno type="Wing">C695</idno>
<idno type="oldCat">
  <g ref="#sym"/>345
</idno>
```

In the last case, the identifier includes a non-Unicode character which is defined elsewhere by means of a <glyph> or <char> element referenced here as `#sym`.

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
  <elementRef key="idno"/>
 </alternate>
</content>
```

Schema Declaration

```
element idno

Contained by iso-fs: vDefault

May contain

iso-fs: binary default f fs numeric string symbol then vAlt vColl vLabel vMerge vNot

Note May contain a feature structure, followed by a feature value; the two are separated by a <then> element.

Example

```
<vDefault>
  <if>
    <fs>
      <f  name="VFORM">
        <symbol  value="INF"/>
      </f>
      <f  name="SUBJ">
        <binary  value="true"/>
      </f>
    </fs>
    <then/>
    <symbol  value="for"/>
  </if>
</vDefault>
```

Content model

```
<content>
 <sequence>
  <alternate>
   <elementRef key="fs"/>
   <elementRef key="f"/>
  </alternate>
  <elementRef key="then"/>
  <classRef key="model.featureVal"/>
 </sequence>
</content>
```

Schema Declaration

```
element if
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   ( ( fs | f ), then, model.featureVal )
}
```

<iff> (if and only if) separates the condition from the consequence in a <bicond> element. [*19.11. Feature System Declaration*]

`@indexName` a single word which follows the rules defining a legal XML name (see `https://www.w3.org/TR/REC-xml/#dt-name`), supplying a name to specify which index (of several) the index entry belongs to.

Status Optional

Datatype teidata.name

Note This attribute makes it possible to create multiple indexes for a text.

  - att.global.source
    - *@source*

`@value` indicates an intermediate node, which is a feature structure or other analytic element.
Status Optional
Datatype teidata.pointer

`@children` provides a list of identifiers of the elements which are the children of the intermediate node.
Status Required
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

`@parent` provides the identifier of the element which is the parent of this node.
Status Optional
Datatype teidata.pointer

`@ord` (ordered) indicates whether or not the internal node is ordered.
Status Optional
Datatype teidata.xTruthValue
Note The value true indicates that the children of the intermediate node are ordered, whereas false indicates the are unordered.
Use if and only if *ord* is specified as partial on the <tree> element and the intermediate node has more than one child.

`@follow` provides the identifier of an element which this node follows.
Status Optional
Datatype teidata.pointer
Note If the tree is unordered or partially ordered, this attribute has the property of fixing the relative order of the intermediate node and the element which is the value of the attribute.

`@outDegree` gives the out degree of an intermediate node, the number of its children.
Status Optional
Datatype teidata.count
Note The in degree of an intermediate node is always 1.

Contained by tree
May contain
core: label
Example

```
<iNode xml:id="pt1" children="#GD-UP1"
  parent="#GD-VB1" follow="#GD-PN1" outDegree="1">
  <label>PT</label>
</iNode>
```

- att.typed
- ~~type~~
- @subtype

`@type` specifies the degree of interaction between active and passive participants in the text.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Legal values are: **none** no interaction of any kind, e.g. a monologue
partial some degree of interaction, e.g. a monologue with set responses
complete complete interaction, e.g. a face to face conversation
inapplicable this parameter is inappropriate or inapplicable in this case

`@active` specifies the number of active participants (or *addressors*) producing parts of the text.
Status Optional
Datatype teidata.enumerated
Suggested values include: **singular** a single addressor
plural many addressors
corporate a corporate addressor
unknown number of addressors unknown or unspecifiable

`@passive` specifies the number of passive participants (or *addressees*) to whom a text is directed or in whose presence it is created or performed.
Status Optional
Datatype teidata.enumerated
Suggested values include: **self** text is addressed to the originator e.g. a diary
single text is addressed to one other person e.g. a personal letter
many text is addressed to a countable number of others e.g. a conversation in which all participants are identified
group text is addressed to an undefined but fixed number of participants e.g. a lecture
world text is addressed to an undefined and indeterminately large number e.g. a published book

Member of model.contentPart

Contained by

tagdocs: alternate content interleave sequence

May contain

tagdocs: alternate anyElement classRef dataRef elementRef empty interleave macroRef sequence textNode

Note If an ODD file makes use of this element, current processing software will not be able to generate a DTD from it. For this reason TEI P5 itself does not currently make use of <interleave> internally.

Example

```
<content>
 <interleave>
   <elementRef  key="persName"/>
   <alternate  minOccurs="0">
     <elementRef  key="placeName"/>
     <elementRef  key="location"/>
```

```
    </alternate>
    <elementRef  key="note"  minOccurs="0"/>
  </interleave>
</content>
```

This example describes a content model that consists of a mandatory <persName> element, zero or one of either <placeName> or <location>, and an optional <note> element, in any order.To express this content model in a DTD, the original schema language for XML, one might use

```
(   persName
      | ( persName, note )
      | ( persName, ( placeName | location ) )
      | ( note, persName )
      | ( ( placeName | location ), persName )
      | ( persName, note, ( placeName | location ) )
      | ( persName, ( placeName | location ), note )
      | ( note, persName, ( placeName | location ) )
      | ( note, ( placeName | location ), persName )
      | ( ( placeName | location ), note, persName )
      | ( ( placeName | location ), persName, note )
    )
```

Schematron <sch:rule context="tei:interleave"> <sch:assert test="count(*) gt 1">The <interleave> element must have at least two child elements.</sch:assert> </sch:rule>

Content model

```
<content>
 <classRef key="model.contentPart"
  minOccurs="1" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element interleave
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.repeatable.attributes,
   model.contentPart+
}
```

<interp> (interpretation) summarizes a specific interpretative annotation which can be linked to a span of text. [*18.3. Spans and Interpretations*]

character data

Note Generally, each <interp> element carries an *xml:id* attribute. This permits the encoder to explicitly associate the interpretation represented by the content of an <interp> with any textual element through its *ana* attribute.

Alternatively (or, in addition) an <interp> may carry an *inst* attribute that points to one or more textual elements to which the analysis represented by the content of the <interp> applies.

Example

```
<interp  type="structuralunit"
  xml:id="ana_am">aftermath</interp>
```

Content model

```
<content>
 <alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
  <classRef key="model.descLike"/>
  <classRef key="model.certLike"/>
 </alternate>
```

```
</content>
```

Schema Declaration

```
element interp
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.cmc.attributes,
   att.interpLike.attributes,
   ( text | model.gLike | model.descLike | model.certLike )*
}
```

<interpGrp> (interpretation group) collects together a set of related interpretations which share responsibility or type. [*18.3. Spans and Interpretations*]

character data

Note May contain simple prose or a sequence of chunks.

Whatever string of characters is used to label a list item in the copy text may be used as the value of the global *n* attribute, but it is not required that numbering be recorded explicitly. In ordered lists, the *n* attribute on the <item> element is by definition synonymous with the use of the <label> element to record the enumerator of the list item. In glossary lists, however, the term being defined should be given with the <label> element, not *n*.

Example

```
<list  rend="numbered">
  <head>Here begin the chapter headings of Book IV</head>
  <item  n="4.1">The death of Queen Clotild.</item>
  <item  n="4.2">How King Lothar wanted to appropriate one third of the Church
revenues.</item>
  <item  n="4.3">The wives and children of Lothar.</item>
  <item  n="4.4">The Counts of the Bretons.</item>
  <item  n="4.5">Saint Gall the Bishop.</item>
  <item  n="4.6">The priest Cato.</item>
  <item> ...</item>
</list>
```

Content model

  - ~~type~~

– @subtype

`@type` indicates the type of indicator used to specify the inflection class, when it is necessary to distinguish between the usual abbreviated indications (e.g. *inv*) and other kinds of indicators, such as special codes referring to conjugation patterns, etc.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Sample values include: **abbrev** abbreviated indicator
verbTable coded reference to a table of verbs
Note This element is synonymous with <gram type='inflectional type'>.

  - *@subtype*

`@result` specifies the name of an element which this aggregation may be understood to represent.
Status Optional
Datatype teidata.name

`@scope` indicates whether the targets to be joined include the entire element indicated (the entire subtree including its root), or just the children of the target (the branches of the subtree).
Status Recommended
Datatype teidata.enumerated
Legal values are: **root** the rooted subtrees indicated by the *target* attribute are joined, each subtree become a child of the virtual element created by the join[Default]
branches the children of the subtrees indicated by the *target* attribute become the children of the virtual element (i.e. the roots of the subtrees are discarded)

verse: metSym rhyme

May contain

certainty: certainty precision respons

core: desc

Example The following example is discussed in section *17.7. Aggregation*:

```
<sp>
  <speaker>Hughie</speaker>
  <p>How does it go? <q>
     <l  xml:id="frog_x1">da-da-da</l>
     <l  xml:id="frog_l2">gets a new frog</l>
     <l>...</l>
   </q>
  </p>
</sp>
<sp>
  <speaker>Louie</speaker>
  <p>
    <q>
     <l  xml:id="frog_l1">When the old pond</l>
     <l>...</l>
    </q>
  </p>
</sp>
<sp>
  <speaker>Dewey</speaker>
  <p>
    <q>... <l  xml:id="frog_l3">It's a new pond.</l>
    </q>
  </p>
```

```
  <join  target="#frog_l1 #frog_l2 #frog_l3"
    result="lg"  scope="root"/>
</sp>
```

The <join> element here identifies a linegroup (<lg>) comprising the three lines indicated by the *target* attribute. The value root for the *scope* attribute indicates that the resulting virtual element contains the three <l> elements linked to at #frog_l1 #frog_l2 #frog_l3, rather than their character data content.

Example In this example, the attribute *scope* is specified with the value of branches to indicate that the virtual list being constructed is to be made by taking the lists indicated by the *target* attribute of the <join> element, discarding the <list> tags which enclose them, and combining the items contained within the lists into a single virtual list:

```
<p>Southern dialect (my own variety, at least) has only <list  xml:id="LP1">
    <item>
      <s>I done gone</s>
    </item>
    <item>
      <s>I done went</s>
    </item>
  </list> whereas Negro Non-Standard basilect has both these and
<list  xml:id="LP2">
    <item>
      <s>I done go</s>
    </item>
  </list>.</p>
<p>White Southern dialect also has <list  xml:id="LP3">
    <item>
      <s>I've done gone</s>
    </item>
    <item>
      <s>I've done went</s>
    </item>
  </list> which, when they occur in Negro dialect, should probably be
considered as borrowings from other varieties of English.</p>
<join  result="list"  xml:id="LST1"
  target="#LP1 #LP2 #LP3"  scope="branches">
  <desc>Sample sentences in Southern speech</desc>
</join>
```

Schematron <sch:rule context="tei:join"> <sch:assert test="contains(normalize-space(@target),' ')"> You must supply at least two values for @target on «sch:name/». </sch:assert> </sch:rule>

Content model

```
<content>
 <alternate minOccurs="0"

`@scheme` identifies the controlled vocabulary within which the set of keywords concerned is defined, for example by a <taxonomy> element, or by some other resource.

Status Optional

Datatype teidata.pointer

Contained by: textClass

May contain

core: list term

Note Each individual keyword (including compound subject headings) should be supplied as a <term> element directly within the <keywords> element. An alternative usage, in which each <term> appears within an <item> inside a <list> is permitted for backwards compatibility, but is deprecated.

If no control list exists for the keywords used, then no value should be supplied for the *scheme* attribute.

Example

```
<keywords  scheme="http://classificationweb.net">
  <term>Babbage, Charles</term>
  <term>Mathematicians - Great Britain - Biography</term>
</keywords>
```

Example

```
<keywords>
  <term>Fermented beverages</term>
  <term>Central Andes</term>
  <term>Schinus molle</term>
  <term>Molle beer</term>
  <term>Indigenous peoples</term>
  <term>Ethnography</term>
  <term>Archaeology</term>
</keywords>
```

Content model

```
<content>
 <alternate>
  <elementRef key="term" minOccurs="1"
   maxOccurs="unbounded"/>
  <elementRef key="list"/>
 </alternate>
</content>
```

character data

Example Labels are commonly used for the headwords in glossary lists; note the use of the global *xml:lang* attribute to set the default language of the glossary list to Middle English, and identify the glosses and headings as modern English or Latin:

```
<list type="gloss" xml:lang="enm">
  <head xml:lang="en">Vocabulary</head>
  <headLabel xml:lang="en">Middle English</headLabel>
  <headItem xml:lang="en">New English</headItem>
  <label>nu</label>
  <item xml:lang="en">now</item>
  <label>lhude</label>
  <item xml:lang="en">loudly</item>
  <label>bloweth</label>
  <item xml:lang="en">blooms</item>
  <label>med</label>
  <item xml:lang="en">meadow</item>
  <label>wude</label>
  <item xml:lang="en">wood</item>
  <label>awe</label>
  <item xml:lang="en">ewe</item>
  <label>lhouth</label>
  <item xml:lang="en">lows</item>
  <label>sterteth</label>
  <item xml:lang="en">bounds, frisks (cf. <cit>
     <ref>Chaucer, K.T.644</ref>
```

```
      <quote>a courser, <term>sterting</term>as the fyr</quote>
    </cit>
  </item>
  <label>verteth</label>
  <item  xml:lang="la">pedit</item>
  <label>murie</label>
  <item  xml:lang="en">merrily</item>
  <label>swik</label>
  <item  xml:lang="en">cease</item>
  <label>naver</label>
  <item  xml:lang="en">never</item>
</list>
```

Example Labels may also be used to record explicitly the numbers or letters which mark list items in ordered lists, as in this extract from Gibbon's *Autobiography*. In this usage the <label> element is synonymous with the *n* attribute on the <item> element:

```
I will add two facts, which have seldom occurred
in the composition of six, or at least of five quartos. <list  rend="runon
numbered">
  <label>(1)</label>
  <item>My first rough manuscript, without any intermediate copy, has been sent
to the press.</item>
  <label>(2) </label>
  <item>Not a sheet has been seen by any human eyes, excepting those of the
author and the
    printer: the faults and the merits are exclusively my own.</item>
</list>
```

Example Labels may also be used for other structured list items, as in this extract from the journal of Edward Gibbon:

```
<list  type="gloss">
  <label>March 1757.</label>
  <item>I wrote some critical observations upon Plautus.</item>
  <label>March 8th.</label>
  <item>I wrote a long dissertation upon some lines of Virgil.</item>
  <label>June.</label>
  <item>I saw Mademoiselle Curchod — <quote  xml:lang="la">Omnia vincit amor,
et nos cedamus
       amori.</quote>
  </item>
  <label>August.</label>
  <item>I went to Crassy, and staid two days.</item>
</list>
```

Note that the <label> might also appear within the <item> rather than as its sibling. Though syntactically valid, this usage is not recommended TEI practice.

Example Labels may also be used to represent a label or heading attached to a paragraph or sequence of paragraphs not treated as a structural division, or to a group of verse lines. Note that, in this case, the <label> element appears *within* the <p> or <lg> element, rather than as a preceding sibling of it.

```
<p>[...]
<lb/>& n'entrer en mauuais & mal-heu-
<lb/>ré meſnage. Or des que le conſente-
<lb/>ment des parties y eſt le mariage eſt
<lb/> arreſté, quoy que de faict il ne ſoit
```

```
<label  place="margin">Puiſſance maritale
    entre les Romains.</label>
  <lb/> conſommé. Depuis la conſomma-
<lb/>tion du mariage la femme eſt ſoubs
<lb/> la puiſſance du mary, s'il n'eſt eſcla-
<lb/>ue ou enfant de famille : car en ce
<lb/> cas, la femme, qui a eſpouſé vn en-
<lb/>fant de famille, eſt ſous la puiſſance
[...]</p>
```

In this example the text of the label appears in the right hand margin of the original source, next to the paragraph it describes, but approximately in the middle of it. If so desired the *type* attribute may be used to distinguish different categories of label.

- att.typed
  - ~~type~~
  - @subtype

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.
Derived from att.typed
Status Optional
Datatype teidata.enumerated
Sample values include: **listening**
speaking
reading
writing

`@tags` supplies one or more valid language tags for the languages specified.
Status Optional
Datatype 1–∞ occurrences of teidata.language separated by whitespace
Note This attribute should be supplied only if the element contains no <langKnown> children. Its values are language 'tags' as defined in RFC 4646 or its successor

Member of model.persStateLike
Contained by

`@ident` (identifier) Supplies a language code constructed as defined in BCP 47 which is used to identify the language documented by this element, and which may be referenced by the global *xml:lang* attribute.
Status Required
Datatype teidata.language

`@usage` specifies the approximate percentage of the text which uses this language.
Status Optional
Datatype nonNegativeInteger

Contained by: header: langUsage

`@columns` (columns) specifies the number of columns per page.

Status Optional

Datatype 1–2 occurrences of teidata.count separated by whitespace

Note If a single number is given, all pages referenced have this number of columns. If two numbers are given, the number of columns per page varies between the values supplied. Where *columns* is omitted the number is assumed to be 1.

Columns may be independent of page orientation or reading direction, and a single textual *stream* may have one or more columns.

`@streams` (textual streams) indicates the number of streams per page, each of which contains an independent textual stream.

Status Optional

Datatype 1–2 occurrences of teidata.count separated by whitespace

Note If a single number is given, all pages referenced have this number of textual streams. If two numbers are given, the number of textual streams per page varies between the values supplied. Where *streams* is omitted the number is assumed to be 1 and unless specified elsewhere the script orientation of the source is identical to that used in the TEI document.

`@ruledLines` (ruled lines) specifies the number of ruled lines per column.

Status Optional

Datatype 1–2 occurrences of teidata.count separated by whitespace

Note If a single number is given, all columns have this number of ruled lines. If two numbers are given, the number of ruled lines per column varies between the values supplied.

`@writtenLines` (written lines) specifies the number of written lines per column.

Status Optional

Datatype 1–2 occurrences of teidata.count separated by whitespace

Note If a single number is given, all columns have this number of written lines. If two numbers are given, the number of written lines per column varies between the values supplied.

May contain Empty element

Note By convention, <lb> elements should appear at the point in the text where a new line starts. The *n* attribute, if used, indicates the number or other value associated with the text between this point and the next <lb> element, typically the sequence number of the line within the page, or other appropriate unit. This element is intended to be used for marking the beginning of each new topographic line on a manuscript or printed page, at the point where it occurs; it should not be used to tag structural units such as lines of verse (for which the <l> element is available) except in circumstances where structural units cannot otherwise be marked.

The *type* attribute may be used to characterize the line beginning in any respect. The more specialized attributes *break*, *ed*, or *edRef* should be preferred when the intent is to indicate whether or not the beginning of the new topographic line is word-breaking, or to note the source from which it derives.

Example This example shows the encoding of the beginning of each new topographic line within a metrical line, indicating where it occurs in both the 1667 and 1674 editions:

```
<l>Of Mans First Disobedience,<lb  ed="1674"/> and<lb  ed="1667"/> the
Fruit</l>
<l>Of that Forbidden Tree, whose<lb  ed="1667 1674"/> mortal tast</l>
<l>Brought Death into the World,<lb  ed="1667"/> and all<lb  ed="1674"/> our
woe,</l>
```

Example This example shows the encoding of the beginning of a new topographical line as a means of preserving the visual appearance of a title page. The *break* attribute is used to show that the beginning of the new line does not (as elsewhere) mark the start of a new word.

```
<titlePart>
  <lb/>With Additions, ne-<lb  break="no"/>ver before Printed.
</titlePart>
```

Content model `<content> <empty/></content>`

character data

Note The term *lemma* is used in text criticism to describe the reading given in the main text, which may be used as a heading in the apparatus itself. This usage connects it to mathematics (where a lemma is a proven proposition used as a step in a proof, a ”given”) and natural-language processing (where a lemma is the dictionary headword associated with an inflected form in the running text).

Example

```
<app>
  <lem  wit="#El #Hg">Experience</lem>
  <rdg  wit="#La"  type="substantive">Experiment</rdg>
  <rdg  wit="#Ra2"  type="substantive">Eryment</rdg>
</app>
```

character data

Note This element should be used only to mark up writing which is topographically organized as a series of lines, horizontal or vertical. It should not be used to mark lines of verse (for which use <l>) nor to mark line beginnings within text which has been encoded using structural elements such as <p> (for which use <lb>).

Example This example shows topographical lines as a means of preserving the visual appearance of a poem:

```
<surface>
  <zone>
    <line>Poem</line>
    <line>As in Visions of — at</line>
```

```
      <line>night —</line>
      <line>All sorts of fancies running through</line>
      <line>the head</line>
    </zone>
  </surface>
```

Example

```
  <surface>
    <zone>
      <line>Hope you enjoyed</line>
      <line>Wales, as they
          said</line>
      <line>to Mrs FitzHerbert</line>
      <line>Mama</line>
    </zone>
    <zone>
      <line>Printed in England</line>
    </zone>
  </surface>
```

Content model

May contain Empty element

Note This element should only be used to encode associations not otherwise provided for by more specific elements.

The location of this element within a document has no significance, unless it is included within a <linkGrp>, in which case it may inherit the value of the *type* attribute from the value given on the <linkGrp>.

Example

```
<s  n="1">The state Supreme Court has refused to release <rs  xml:id="R1">
    <rs  xml:id="R2">Rahway State Prison</rs> inmate</rs>
  <rs  xml:id="R3">James Scott</rs> on bail.</s>
<s  n="2">
  <rs  xml:id="R4">The fighter</rs> is serving 30-40 years
for a 1975 armed robbery conviction in <rs  xml:id="R5">the penitentiary</rs>.
</s>
<!-- ... -->
<linkGrp  type="periphrasis">
  <link  target="#R1 #R3 #R4"/>
```

```
  <link  target="#R2 #R5"/>
</linkGrp>
```

Schematron <sch:rule context="tei:link"> <sch:assert test="contains(normalize-space(@target),' ')">You must supply at least two values for @target on «sch:name/».</sch:assert> </sch:rule>

Content model `<content> <empty/></content>`

Schema Declaration

```

May contain

core: desc ptr

linking: link

Note May contain one or more <link> or <ptr> elements.

A web or link group is an administrative convenience, which should be used to collect a set of links together for any purpose, not simply to supply a default value for the *type* attribute.

Example

```
<linkGrp  type="translation">
  <link  target="#CCS1 #SW1"/>
  <link  target="#CCS2 #SW2"/>
  <link  target="#CCS #SW"/>
</linkGrp>
<div  type="volume"  xml:id="CCS"
  xml:lang="fr">
  <p>
    <s  xml:id="CCS1">Longtemps, je me suis couché de bonne heure.</s>
    <s  xml:id="CCS2">Parfois, à peine ma bougie éteinte, mes yeux se fermaient
si vite que je n'avais pas le temps de me dire : "Je m'endors."</s>
  </p>
<!-- ... -->
</div>
<div  type="volume"  xml:id="SW"  xml:lang="en">
  <p>
    <s  xml:id="SW1">For a long time I used to go to bed early.</s>
    <s  xml:id="SW2">Sometimes, when I had put out my candle, my eyes would
close so quickly that I had not even time to say "I'm going to sleep."</s>
  </p>
<!-- ... -->
</div>
```

  - ~~type~~
  - @subtype

`@type` (type) describes the nature of the items in the list.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: **gloss** (gloss) each list item glosses some term or concept, which is given by a <label> element preceding the list item.

index (index) each list item is an entry in an index such as the alphabetical topical index at the back of a print volume.

instructions (instructions) each list item is a step in a sequence of instructions, as in a recipe.

litany (litany) each list item is one of a sequence of petitions, supplications or invocations, typically in a religious ritual.

syllogism (syllogism) each list item is part of an argument consisting of two or more propositions and a final conclusion derived from them.

Note Previous versions of these Guidelines recommended the use of *type* on <list> to encode the rendering or appearance of a list (whether it was bulleted, numbered, etc.). The current recommendation is to use the *rend* or *style* attributes for these aspects of a list, while using *type* for the more appropriate task of characterizing the nature of the content of a list.

The formal syntax of the element declarations allows <label> tags to be omitted from lists tagged <list type="gloss">; this is however a semantic error.

Note May contain an optional heading followed by a series of items, or a series of label and item pairs, the latter being optionally preceded by one or two specialized headings.

Example

```
<list  rend="numbered">
  <item>a butcher</item>
  <item>a baker</item>
  <item>a candlestick maker, with
  <list  rend="bulleted">
     <item>rings on his fingers</item>
     <item>bells on his toes</item>
   </list>
  </item>
</list>
```

Example

```
<list  type="syllogism"  rend="bulleted">
  <item>All Cretans are liars.</item>
  <item>Epimenides is a Cretan.</item>
  <item>ERGO Epimenides is a liar.</item>
</list>
```

Example

```
<list  type="litany"  rend="simple">
  <item>God save us from drought.</item>
  <item>God save us from pestilence.</item>
```

```
  <item>God save us from wickedness in high places.</item>
  <item>Praise be to God.</item>
</list>
```

Example The following example treats the short numbered clauses of Anglo-Saxon legal codes as lists of items. The text is from an ordinance of King Athelstan (924–939):

```
<div1 type="section">
  <head>Athelstan's Ordinance</head>
  <list rend="numbered">
    <item n="1">Concerning thieves. First, that no thief is to be spared who is
caught with
       the stolen goods, [if he is] over twelve years and [if the value of the
goods is] over
       eightpence.
   <list rend="numbered">
      <item n="1.1">And if anyone does spare one, he is to pay for the thief
with his
              wergild — and the thief is to be no nearer a settlement on that
account — or to
              clear himself by an oath of that amount.</item>
      <item n="1.2">If, however, he [the thief] wishes to defend himself or to
escape, he is
              not to be spared [whether younger or older than twelve].</item>
      <item n="1.3">If a thief is put into prison, he is to be in prison 40
days, and he may
              then be redeemed with 120 shillings; and the kindred are to stand
surety for him
              that he will desist for ever.</item>
      <item n="1.4">And if he steals after that, they are to pay for him with
his wergild,
              or to bring him back there.</item>
      <item n="1.5">And if he steals after that, they are to pay for him with
his wergild,
              whether to the king or to him to whom it rightly belongs; and
everyone of those who
              supported him is to pay 120 shillings to the king as a
fine.</item>
    </list>
   </item>
   <item n="2">Concerning lordless men. And we pronounced about these lordless
men, from whom
       no justice can be obtained, that one should order their kindred to
fetch back such a
       person to justice and to find him a lord in public meeting.
   <list rend="numbered">
      <item n="2.1">And if they then will not, or cannot, produce him on that
appointed day,
              he is then to be a fugitive afterwards, and he who encounters him
is to strike him
              down as a thief.</item>
      <item n="2.2">And he who harbours him after that, is to pay for him with
his wergild
              or to clear himself by an oath of that amount.</item>
    </list>
   </item>
   <item n="3">Concerning the refusal of justice. The lord who refuses justice
```

```
and upholds
        his guilty man, so that the king is appealed to, is to repay the value
of the goods and
        120 shillings to the king; and he who appeals to the king before he
demands justice as
        often as he ought, is to pay the same fine as the other would have
done, if he had
        refused him justice.
   <list  rend="numbered">
      <item  n="3.1">And the lord who is an accessory to a theft by his slave,
and it becomes
              known about him, is to forfeit the slave and be liable to his
wergild on the first
              occasionp if he does it more often, he is to be liable to pay all
that he owns.</item>
      <item  n="3.2">And likewise any of the king's treasurers or of our
reeves, who has been
              an accessory of thieves who have committed theft, is to liable to
the same.</item>
    </list>
   </item>
   <item  n="4">Concerning treachery to a lord. And we have pronounced
concerning treachery to
        a lord, that he [who is accused] is to forfeit his life if he cannot
deny it or is
        afterwards convicted at the three-fold ordeal.</item>
  </list>
</div1>
```

Note that nested lists have been used so the tagging mirrors the structure indicated by the two-level numbering of the clauses. The clauses could have been treated as a one-level list with irregular numbering, if desired.

Example

```
<p>These decrees, most blessed Pope Hadrian, we propounded in the public
council ... and they
confirmed them in our hand in your stead with the sign of the Holy Cross, and
afterwards
inscribed with a careful pen on the paper of this page, affixing thus the sign
of the Holy
Cross.
<list  rend="simple">
   <item>I, Eanbald, by the grace of God archbishop of the holy church of
York, have
        subscribed to the pious and catholic validity of this document with the
sign of the Holy
        Cross.</item>
   <item>I, Ælfwold, king of the people across the Humber, consenting have
subscribed with
        the sign of the Holy Cross.</item>
   <item>I, Tilberht, prelate of the church of Hexham, rejoicing have
subscribed with the
        sign of the Holy Cross.</item>
   <item>I, Higbald, bishop of the church of Lindisfarne, obeying have
subscribed with the
        sign of the Holy Cross.</item>
```

```
      <item>I, Ethelbert, bishop of Candida Casa, suppliant, have subscribed with
    thef sign of
          the Holy Cross.</item>
      <item>I, Ealdwulf, bishop of the church of Mayo, have subscribed with
    devout will.</item>
      <item>I, Æthelwine, bishop, have subscribed through delegates.</item>
      <item>I, Sicga, patrician, have subscribed with serene mind with the sign
    of the Holy
          Cross.</item>
    </list>
  </p>
```

Schematron <sch:rule context="tei:list[@type='gloss']"> <sch:assert test="tei:label"> The content of a "gloss" list should include a sequence of one or more pairs of a <label> element followed by an <item> element. </sch:assert> </sch:rule>

May contain
core: desc

header: change listChange

Note When this element appears within the <creation> element it documents the set of revision campaigns or stages identified during the evolution of the original text. When it appears within the <revisionDesc> element, it documents only changes made during the evolution of the encoded representation of that text.

Example

```
<revisionDesc>
  <listChange>
    <change  when="1991-11-11"  who="#LB"> deleted chapter 10 </change>
    <change  when="1991-11-02"  who="#MSM"> completed first draft </change>
  </listChange>
</revisionDesc>
```

Example

```
<profileDesc>
  <creation>
    <listChange  ordered="true">
      <change  xml:id="CHG-1">First stage, written in ink by a writer</change>
      <change  xml:id="CHG-2">Second stage, written in Goethe's hand using
pencil</change>
     <change  xml:id="CHG-3">Fixation of the revised passages and further
revisions by
           Goethe using ink</change>
     <change  xml:id="CHG-4">Addition of another stanza in a different hand,
           probably at a later stage</change>
    </listChange>
  </creation>
</profileDesc>
```

  <head>Battles of the American Civil War: Kentucky</head>
  <event  xml:id="event01"  when="1861-09-19">
    <label>Barbourville</label>
    <desc>The Battle of Barbourville was one of the early engagements of
        the American Civil War. It occurred September 19, 1861, in Knox
        County, Kentucky during the campaign known as the Kentucky Confederate
        Offensive. The battle is considered the first Confederate victory in
        the commonwealth, and threw a scare into Federal commanders, who
        rushed troops to central Kentucky in an effort to repel the invasion,
        which was finally thwarted at the <ref  target="#event02">Battle of
           Camp Wildcat</ref> in October.</desc>
  </event>
  <event  xml:id="event02"  when="1861-10-21">
    <label>Camp Wild Cat</label>
    <desc>The Battle of Camp Wildcat (also known as Wildcat Mountain and Camp
        Wild Cat) was one of the early engagements of the American Civil
        War. It occurred October 21, 1861, in northern Laurel County, Kentucky
        during the campaign known as the Kentucky Confederate Offensive. The
        battle is considered one of the very first Union victories, and marked
```

```
        the first engagement of troops in the commonwealth of Kentucky.</desc>

Note The *type* attribute may be used to distinguish different types of objects.

Example

```
<listObject>
  <object xml:id="AlfredJewel">
    <objectIdentifier>
      <country>United Kingdom</country>
      <region>Oxfordshire</region>
      <settlement>Oxford</settlement>
```

```
      <institution>University of Oxford</institution>
      <repository>Ashmolean Museum</repository>
      <collection>English Treasures</collection>
      <idno  type="ashmolean">AN1836p.135.371</idno>
      <idno  type="wikipedia">https://en.wikipedia.org/wiki/Alfred_Jewel</idno>
      <objectName>Alfred Jewel</objectName>
    </objectIdentifier>
    <physDesc>
      <p> The Alfred Jewel is about 6.4 cm in length and is made of combination
of filigreed <material>gold</material>
           surrounding a polished teardrop shaped piece of transparent
<material>quartz</material>. Underneath the rock crystal
           is a cloisonné enamel image of a man with ecclesiastical symbols.
The sides of the jewel holding the crystal in
           place contain an openwork inscription saying "AELFRED MEC HEHT
GEWYRCAN", meaning 'Alfred ordered me made'. </p>
    </physDesc>
    <history>
      <origin>It is generally accepted that the Alfred Jewel dates from the
<origDate>late 9th Century</origDate> and was
           most likely made in <origPlace>England</origPlace>. </origin>
      <provenance  when="1693">The jewel was discovered in 1693 at Petherton
Park, North Petherton in the English county of
           Somerset, on land owned by Sir Thomas Wroth. North Petherton is
about 8 miles away from Athelney, where King Alfred
           founded a monastery. </provenance>
      <provenance  when="1698">A description of the Alfred Jewel was first
published in 1698, in the Philosophical
           Transactions of the Royal Society.</provenance>
      <acquisition> It was bequeathed to Oxford University by Colonel Nathaniel
Palmer (c. 1661-1718) and today is in the
           Ashmolean Museum in Oxford. </acquisition>
    </history>
  </object>

header: listPrefixDef prefixDef

Example In this example, two private URI scheme prefixes are defined and patterns are provided for dereferencing them. Each prefix is also supplied with a human-readable explanation in a <p> element.

```
<listPrefixDef>
  <prefixDef  ident="psn"
    matchPattern="([A-Z]+)"
    replacementPattern="personography.xml#$1">
    <p> Private URIs using the <code>psn</code>
        prefix are pointers to <gi>person</gi>
        elements in the personography.xml file.
        For example, <code>psn:MDH</code>
        dereferences to <code>personography.xml#MDH</code>.
    </p>
  </prefixDef>
  <prefixDef  ident="bibl"
    matchPattern="([a-z]+[a-z0-9]*)"
    replacementPattern="http://www.example.com/getBibl.xql?id=$1">
    <p> Private URIs using the <code>bibl</code> prefix can be
        expanded to form URIs which retrieve the relevant
        bibliographical reference from www.example.com.
    </p>
  </prefixDef>
</listPrefixDef>
```

Content model

transcr: damage metamark mod restore retrace secl supplied surplus

verse: rhyme

May contain

core: desc head p

linking: ab

namesdates: listRelation relation

Note May contain a prose description organized as paragraphs, or a sequence of <relation> elements.

Example

```
<listPerson>
  <person xml:id="pp1">
<!-- data about person pp1 -->
  </person>
  <person xml:id="pp2">
<!-- data about person pp1 -->
  </person>
<!-- more person (pp3, pp4) elements here -->
  <listRelation type="personal">
    <relation name="parent"
      active="#pp1 #pp2" passive="#pp3 #pp4"/>
    <relation name="spouse"
      mutual="#pp1 #pp2"/>
  </listRelation>
  <listRelation type="social">
    <relation name="employer" active="#pp1"
      passive="#pp3 #pp5 #pp6 #pp7"/>
  </listRelation>
</listPerson>
```

The persons with identifiers pp1 and pp2 are the parents of pp3 and pp4; they are also married to each other; pp1 is the employer of pp3, pp5, pp6, and pp7.

Example

```
<listPerson>
  <person xml:id="en_pp1">
<!-- data about person en_pp1 -->
  </person>
  <person xml:id="en_pp2">
<!-- data about person en_pp2 -->
  </person>
<!-- more person (en_pp3, en_pp4) elements here -->
</listPerson>
<listPlace>
  <place xml:id="en_pl1">
<!-- data about place en_pl1 -->
  </place>
<!-- more place (en_pl2, en_pl3) elements here -->
</listPlace>
<listRelation>
```

```
  <relation  name="residence"
    active="#en_pp1 #en_pp2"  passive="#en_pl1"/>
</listRelation>
```

The persons with identifiers en_pp1 and en_pp2 live in en_pl1.

Example

```
<listRelation>
  <p>All speakers are members of the Ceruli family, born in Naples.</p>
</listRelation>
```

Content model

```
<content>
 <sequence>
  <classRef key="model.headLike"
   minOccurs="0" maxOccurs="unbounded"/>
  <elementRef key="desc" minOccurs="0"
   maxOccurs="unbounded"/>

transcr: damage metamark mod restore retrace secl supplied surplus

verse: rhyme

May contain

core: desc head

textcrit: listWit witness

Note May contain a series of <witness> or <listWit> elements.

The provision of a <listWit> element simplifies the automatic processing of the apparatus, e.g. the reconstruction of the readings for all witnesses from an exhaustive apparatus.

Situations commonly arise where there are many more or less fragmentary witnesses, such that there may be quite distinct groups of witnesses for different parts of a text or collection of texts. Such groups may be given separately, or nested within a single <listWit> element at the beginning of the file listing all the witnesses, partial and complete, for the text, with the attestation of fragmentary witnesses indicated within the apparatus by use of the <witStart> and <witEnd> elements described in section *13.1.5. Fragmentary Witnesses*.

Note however that a given witness can only be defined once, and can therefore only appear within a single <listWit> element.

Example

```
<listWit>
  <witness  xml:id="HL26">Ellesmere, Huntingdon Library 26.C.9</witness>
  <witness  xml:id="PN392">Hengwrt, National Library of Wales,
     Aberystwyth, Peniarth 392D</witness>
  <witness  xml:id="RP149">Bodleian Library Rawlinson Poetic 149
     (see further <ptr  target="#MSRP149"/>)</witness>
</listWit>
```

Content model

```
<content>
 <sequence>
  <classRef key="model.headLike"
```

```
   minOccurs="0"/>
  <elementRef key="desc" minOccurs="0"
   maxOccurs="unbounded"/>
  <alternate minOccurs="1"
   maxOccurs="unbounded">
   <elementRef key="witness"/>
   <elementRef key="listWit"/>
  </alternate>
 </sequence>
</content>
```

Schema Declaration

```
element listWit
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.sortable.attributes,
   ( model.headLike?, desc*, ( witness | listWit )+ )
}
```

<locale> contains a brief informal description of the kind of place concerned, for example: a room, a restaurant, a park bench, etc. [*16.2.3. The Setting Description*]

`@scheme` (scheme) identifies the foliation scheme in terms of which the location is being specified by pointing to some <foliation> element defining it, or to some other equivalent resource.
Status Optional
Datatype teidata.pointer

`@from` (from) specifies the starting point of the location in a normalized form, typically a page number.
Status Optional
Datatype teidata.word

`@to` (to) specifies the end-point of the location in a normalized form, typically as a page number.
Status Optional
Datatype teidata.word

msdescription: locus

character data

Note The *target* attribute should only be used to point to elements that contain or indicate a transcription of the locus being described, as in the 'Ben Jonson' example.

To associate a <locus> element with a page image or other comparable representation, the global *facs* attribute should be used, as shown in the 'Birds Praise of Love' example. The *facs* attribute may be used to indicate one or more image files, as in that example, or alternatively it may point to one or more appropriate XML elements, such as the <surface>, <zone>, <graphic>, or <binaryObject> elements.

When a single page is being cited, use the *from* and *to* attributes with an identical value. When no clear endpoint is provided, the *from* attribute may be used without *to*; for example a citation such as 'p. 3ff' might be encoded `<locus from="3">p. 3ff</locus>`.

Example

```
<!-- within ms description --><msItem  n="1">
  <locus  target="#F1r #F1v #F2r"  from="1r"
    to="2r">ff. 1r-2r</locus>
  <author>Ben Jonson</author>
  <title>Ode to himself</title>
  <rubric  rend="italics"> An Ode<lb/> to him selfe.</rubric>
  <incipit>Com leaue the loathed stage</incipit>
  <explicit>And see his chariot triumph ore his wayne.</explicit>
  <bibl>
    <name>Beal</name>, <title>Index 1450-1625</title>, JnB 380</bibl>
</msItem>
<!-- within transcription ... -->
<pb  xml:id="F1r"/>
<!-- ... -->
<pb  xml:id="F1v"/>
<!-- ... -->
<pb  xml:id="F2r"/>
<!-- ... -->
```

Example The *facs* attribute is available globally when the `transcr` module is included in a schema. It may be used to point directly to an image file, as in the following example:

```
<msItem>
  <locus  facs="images/08v.jpg images/09r.jpg images/09v.jpg images/10r.jpg
images/10v.jpg">fols. 8v-10v</locus>
  <title>Birds Praise of Love</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>1506</biblScope>
  </bibl>
</msItem>
```

Content model

```
<content>

`@function` describes the function or use of the material in relation to the object as a whole.
Status Optional
Datatype teidata.enumerated
Sample values include: **binding** covering material of a codex
endband sewing at the head or tail of the codex spine to strengthen the binding, often decorative
slipcase removable protective cover for a set of one or more codices
support the surface for writing
tie a ribbon or string used to bind or close a codex or rolled scroll
Note The sample values here are for descriptive bibliography. Other sets of sample values might include armrests, legs, tabletop, pan, and back for furniture; or wall, floor, window, column, ceiling, roof, stairs, chimney for architecture.

`@target` identifies one or more elements to which the metamark applies.
Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

character data

Note The *ref* attribute may be used to point to one or more items within a taxonomy of types of material, defined either internally or externally.

Example

```
<physDesc>
  <p>
    <material>Parchment</material> leaves with a
  <material>sharkskin</material> binding.</p>
</physDesc>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element material
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
```

```
   att.global.source.attributes,
   att.canonical.attributes,
   att.typed.attributes,
   attribute function { text }?,
   attribute target { list { + } }?,
   macro.phraseSeq}
```

<measure> (measure) contains a word or phrase referring to some quantity of an object or commodity, usually comprising a number, a unit, and a commodity name. [*3.6.3. Numbers and Measures*]

character data

Example This example references a definition of a measurement unit declared in the TEI header:

```
<measure type="weight">
  <num>2</num> pounds of flesh
</measure>
<measure type="currency">£10-11-6d</measure>
<measure type="area" unitRef="#merk">2 <unit>merks</unit> of old
extent</measure>
<!-- In the TEI Header: -->
<encodingDesc>
  <unitDecl>
    <unitDef xml:id="merk" type="area">
      <label>merk</label>
      <placeName ref="#Scotland"/>
      <desc>A merk was an area of land determined variably by its agricultural
            productivity.</desc>
    </unitDef>
  </unitDecl>
</encodingDesc>
```

Example

```
<measure quantity="40" unit="hogshead"
  commodity="rum">2 score hh rum</measure>
<measure quantity="12" unit="count"
  commodity="roses">1 doz. roses</measure>
<measure quantity="1" unit="count"
  commodity="tulips">a yellow tulip</measure>
```

Example

```
<head>Long papers.</head>
<p>Speakers will be given 30 minutes each: 20 minutes for
presentation, 10 minutes for discussion. Proposals should not
exceed <measure max="500" unit="count"
    commodity="words">500
     words</measure>. This presentation type is suitable for
substantial research, theoretical or critical discussions.</p>
```

Content model

```
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```
element measure
{
   att.global.attributes,
   att.global.analytic.attributes,

Note The attributes available for this element are not appropriate in all cases. For example, it makes no sense to specify the temporal duration of a graphic. Such errors are not currently detected.

The *mimeType* attribute must be used to specify the MIME media type of the resource specified by the *url* attribute.

Example

```
<figure>
  <media  mimeType="image/png"  url="fig1.png"/>
  <head>Figure One: The View from the Bridge</head>
  <figDesc>A Whistleresque view showing four or five sailing boats in the
foreground, and a
     series of buoys strung out between them.</figDesc>
</figure>
```

Example

```
<media  mimeType="audio/wav"
  url="dingDong.wav"  dur="PT10S">
  <desc>Ten seconds of bellringing sound</desc>
</media>
```

Example

```
<media  mimeType="video/mp4"
  url="clip45.mp4"  dur="PT45M"  width="500px">
  <desc>A 45 minute video clip to be displayed in a window 500
     px wide</desc>
</media>
```

`@key` specifies the identifier for a class of which the documented element or class is a member or subclass.
Status Optional
Datatype teidata.name

`@mode` specifies the effect of this declaration on its parent module.
Status Optional
Datatype teidata.enumerated
Legal values are: **add** this declaration is added to the current definitions[Default]
delete this declaration and all of its children are removed from the current setup

`@max` supplies the maximum number of times the element can occur in elements which use this model class in their content model
Status Optional
Datatype teidata.numeric

`@min` supplies the minumum number of times the element must occur in elements which use this model class in their content model
Status Optional
Datatype teidata.numeric

Contained by: classes
May contain
gaiji: g
character data

Note Elements or classes which are members of multiple (unrelated) classes will have more than one <memberOf> element, grouped by a <classes> element. If an element is a member of a class C1, which is itself a subclass of a class C2, there is no need to state this, other than in the documentation for class C1.

Any additional comment or explanation of the class membership may be provided as content for this element.

Example

```
<memberOf  key="model.divLike"/>
<memberOf  key="att.identified"/>
```

This element will appear in any content model which references `model.divLike`, and will have attributes defined in `att.identified` (in addition to any defined explicitly for this element).

Content model `<content> <macroRef key="macro.xtext"/></content>`

Schema Declaration

```
element memberOf
{
```

```
   att.global.attributes,

<metamark>

contains or describes any kind of graphic or written signal within a document the function of which is to determine how it should be read rather than forming part of the actual content of the document. [*12.3.4.2. Metamarks*]

Module transcr — Representation of Primary Sources

<metDecl> (metrical notation declaration) documents the notation employed to represent a metrical pattern when this is specified as the value of a *met*, *real*, or *rhyme* attribute on any structural element of a metrical text (e.g. <lg>, <l>, or <seg>). [*6.6. Metrical Notation Declaration 6.4. Rhyme and Metrical Analysis*]

Module verse — Verse

    - *@cert*
    - *@resp*
  - att.global.source
    - *@source*
- att.declarable
  - *@default*

`@type` indicates whether the notation conveys the abstract metrical form, its actual prosodic realization, or the rhyme scheme, or some combination thereof.

Status Optional

Datatype 1–3 occurrences of teidata.enumerated separated by whitespace

Legal values are: **met** (met attribute) declaration applies to the abstract metrical form recorded on the *met* attribute

real (real attribute) declaration applies to the actual realization of the conventional metrical structure recorded on the *real* attribute

rhyme declaration applies to the rhyme scheme recorded on the *rhyme* attribute

Note By default, the <metDecl> element documents the notation used for metrical pattern and realization. It may also be used to document the notation used for rhyme scheme information; if not otherwise documented, the rhyme scheme notation defaults to the traditional 'abab' notation.

`@pattern` (regular expression pattern) specifies a regular expression defining any value that is legal for this notation.

Status Optional

Datatype teidata.pattern

Note The value must be a valid regular expression per the World Wide Web Consortium's XML Schema Part 2: Datatypes Second Edition, Appendix F.

Member of model.encodingDescPart

Contained by

header: encodingDesc

May contain

core: note noteGrp p

linking: ab

verse: metSym

Note The encoder may choose whether to define the notation formally or informally. However, the two methods may not be mixed. That is, <metDecl> may contain either a sequence of <metSym> elements or, alternately, a series of paragraphs or other components. If the *pattern* attribute is specified and <metSym> elements are used, then all the codes appearing within the *pattern* attribute should be documented.

Only usable within the header if the verse module is used.

Example

```
<metDecl  xml:id="ip"  type="met"
  pattern="((SU|US)USUSUSUS/)">
  <metSym  value="S">stressed syllable</metSym>
  <metSym  value="U">unstressed syllable</metSym>
  <metSym  value="/">metrical line boundary</metSym>
</metDecl>
```

This example is intended for the far more restricted case typified by the Shakespearean iambic pentameter. Only metrical patterns containing exactly ten syllables, alternately stressed and unstressed, (except for the first two which may be in either order) to each metrical line can be expressed using this notation.

Schematron <sch:pattern is-a="declarable"> <sch:param name="tde" value="tei:metDecl"/> </sch:pattern>

Content model

```
<content>
 <alternate>
  <alternate minOccurs="1"
   maxOccurs="unbounded">
   <classRef key="model.pLike"/>
   <classRef key="model.noteLike"/>
  </alternate>
```

```
  <elementRef key="metSym" minOccurs="1"
   maxOccurs="unbounded"/>
 </alternate>
</content>
```

Schema Declaration

```
element metDecl
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.declarable.attributes,
   attribute type
   {
      list
      {
         ( "met" | "real" | "rhyme" ),
         ( "met" | "real" | "rhyme" )?,
         ( "met" | "real" | "rhyme" )?
      }
   }?,
   attribute pattern { text }?,
   ( ( model.pLike | model.noteLike )+ | metSym+ )
}
```

<metSym> (metrical notation symbol) documents the intended significance of a particular character or character sequence within a metrical notation, either explicitly or in terms of other <metSym> elements in the same <metDecl>. [*6.6. Metrical Notation Declaration*]

Module verse — Verse

`@value` specifies the character or character sequence being documented.
Status Required
Datatype 1–∞ occurrences of teidata.word separated by whitespace

`@terminal` specifies whether the symbol is defined in terms of other symbols (*terminal* is set to false) or in prose (*terminal* is set to true).
Status Optional
Datatype teidata.truthValue
Default true
Note The value true indicates that the element contains a prose definition of its meaning; the value false indicates that the element contains a definition of its meaning given using symbols defined elsewhere in the same <metDecl> element.

May contain Empty element

Note For this element, the global *n* attribute indicates the new number or other value for the unit which changes at this milestone. The special value *unnumbered* should be used in passages which fall outside the normal numbering scheme, such as chapter or other headings, poem numbers or titles, etc.

The order in which <milestone> elements are given at a given point is not normally significant.

Example

```
<milestone n="23" ed="La" unit="Dreissiger"/>
... <milestone n="24" ed="AV" unit="verse"/> ...
```

Content model `<content> <empty/></content>`

Schema Declaration

`@behaviour` names the process or function which this processing model uses in order to produce output.

Status Required

Datatype teidata.enumerated

Suggested values include: **alternate** (default, alternate) support display of alternative visualisations, for example by displaying the preferred content, by displaying both in parallel, or by toggling between the two.

anchor (id) create an identifiable anchor point in the output.

block (content) create a block structure

body (content) create the body of a document.

break (type, label) create a line, column, or page break according to the value of `type`

cell (content) create a table cell

cit (content, source) show the content, with an indication of the source

document (content) start a new output document

figure (title) make a figure with the *title* as caption

glyph (uri) show a character by looking up reference to a chardesc at the given URI

graphic (url, width, height, scale, title) if `url` is present, uses it to display graphic, else display a placeholder image.

heading (content, level) creates a heading.

index (type) generate list according to `type`.

inline (content, label) creates inline element out of `content`

link (content, uri) create hyperlink

list (content) create a list.

listItem (content) create a list item.

metadata (content) create metadata section

note (content, place, label) create a note, often out of line, depending on the value of `place`; could be margin, footnote, endnote, inline

omit do nothing, do not process children

paragraph (content) create a paragraph out of `content`.

row (content) create a table row

section (content) create a new section of the output document

table (content) create a table

text (content) create literal text

title (content) create document title

`@useSourceRendition` whether to obey any rendition attribute that is present.

Status Optional

Datatype teidata.truthValue

Note If the *useSourceRendition* attribute is not specified, or has the value false, any renditional information specified in the source document should be ignored.

`@output` the intended output.

Status Optional

Datatype teidata.enumerated

Sample values include: **web** the output is intended for presentation in a web format

print the output is intended for presentation in a print format

plain the output is intended for presentation in a plain text format

Note If the *output* attribute is not specified, this model is assumed to apply for all forms of output.

`@cssClass` the name of a CSS class which should be associated with this element

Status Optional

Datatype 1–∞ occurrences of teidata.name separated by whitespace

Contained by tagdocs: elementSpec modelGrp modelSequence

May contain

core: desc gloss

tagdocs: equiv outputRendition param

Note The intended output to be generated for a particular behaviour of a processing model may be documented in one or all of the three following ways. Firstly, the *cssClass* attribute may be used to specify the name of a CSS style in some associated CSS stylesheet which is to be applied to each occurrence of a specified element found (in a given context, for a specified output). Secondly, the attribute *useSourceRendition* may be used to indicate that the default rendition for occurrences of this element, as defined by a <rendition> element in the document header, should be applied. Thirdly, the styling to be applied may be specified explicitly as content of a child <outputRendition> element. When more than one of these options is used, they are understood to be combined in accordance with the rules for multiple declaration of the styling language used.

Example

```
<model behaviour="inline"/>
```

Example

```
<elementSpec mode="change" ident="quote">
  <model predicate="ancestor::p"
    behaviour="inline">
    <desc versionDate="2015-08-21"
      xml:lang="en">If it's inside a paragraph then it's inline</desc>
  </model>
  <model predicate="not(ancestor::p)"
    behaviour="block">
    <desc versionDate="2015-08-21"
      xml:lang="en">If it's not inside a paragraph then it is block level</desc>
  </model>
</elementSpec>
```

Example

```
<model predicate="parent::person"
  behaviour="inline">
  <desc versionDate="2015-08-21"
    xml:lang="en">If it is a child of a person element, treat as inline</desc>
</model>
```

Example

```
<model behaviour="inline">
  <outputRendition>font-weight:bold</outputRendition>
</model>
```

Example

```
<model behaviour="inline" output="print"/>
```

Example

```
<model predicate="ancestor::p"
  behaviour="inline">
  <param name="content" value="@n"/>
</model>
```

Example

```
<elementSpec mode="change" ident="date">
  <model output="print" predicate="text()"
    behaviour="inline"/>
  <model output="print"
    predicate="@when and not(text())" behaviour="inline">
    <param name="content" value="@when"/>
  </model>
  <model predicate="@when" output="web"
    behaviour="alternate">
    <param name="alternate" value="@when"/>
  </model>
</elementSpec>
```

Example

```
<elementSpec mode="change" ident="choice">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
  <model predicate="abbr and expan"
    behaviour="alternate">
    <param name="default" value="expan"/>
    <param name="alternate" value="abbr"/>
  </model>
  <model predicate="orig and reg"
    behaviour="alternate">
    <param name="default" value="reg"/>
    <param name="alternate" value="orig"/>
  </model>
</elementSpec>
```

Schematron It is ambigous to have 2 <model>s that have both the same *output* and have no *predicate* (and thus select the same set of nodes). <sch:rule context="tei:model[not(parent::tei:modelSequence)][not(@predicate)]"> <sch:let name="output" value="normalize-space(@output)"/> <sch:report test="following-sibling::tei:model [not(@predicate)] [normalize-space(@output) eq $output]"> There are 2 (or more) <model> elements in this «sch:value-of select="local-name(..)"/» that have no predicate, but are targeted to the same output ("<sch:value-of select="($output, parent::modelGrp/@output, 'all')[1]"/>"). </sch:report> </sch:rule>

Schematron It is ambigous to have 2 <model>s that have both the same *output* and the same *predicate* (and thus select the same set of nodes). <sch:rule context="tei:model[not(parent::tei:modelSequence)][@predicate]"> <sch:let name="predicate" value="normalize-space(@predicate)"/> <sch:let name="output" value="normalize-space(@output)"/> <sch:report test="following-sibling::tei:model [normalize-space(@predicate) eq $predicate] [normalize-space(@output) eq $output]"> There are 2 (or more) <model> elements in this «sch:value-of select="local-name(..)"/» that have the same predicate, and are targeted to the same output ("<sch:value-of select="($output, parent::modelGrp/@output, 'all')[1]"/>"). </sch:report> </sch:rule>

Content model

```
<content>
 <sequence>
  <alternate minOccurs="0"
   maxOccurs="unbounded">
   <classRef key="model.identEquiv"/>
   <classRef key="model.descLike"/>
  </alternate>
  <elementRef key="param" minOccurs="0"
   maxOccurs="unbounded"/>
  <elementRef key="outputRendition"
   minOccurs="0" maxOccurs="unbounded"/>
 </sequence>
</content>
```

Schema Declaration

```
element model
{
   att.global.attributes,
   att.global.analytic.attributes,

`@useSourceRendition` whether to obey any rendition attribute which is present.
Status Optional
Datatype teidata.truthValue

`@output` the intended output method.
Status Optional
Datatype teidata.enumerated
Suggested values include: **web** the output is intended for presentation in a web format
print the output is intended for presentation in a print format
plaintext the output is intended for presentation in a plain text format

Contained by tagdocs: elementSpec
May contain
core: desc gloss
tagdocs: equiv model modelSequence outputRendition
Note The child <model> elements of a <modelGrp> are always processed independently.
Example

```
<elementSpec mode="change" ident="abbr">
  <modelGrp output="web">
    <model predicate="parent::choice"
      behaviour="omit"/>
    <model predicate="ancestor::front"
      behaviour="inline">
      <outputRendition>font-style:italic; </outputRendition>
    </model>
    <model predicate="not(parent::choice)"
      behaviour="inline">
      <outputRendition scope="before">content: ' ('</outputRendition>
      <outputRendition scope="after">content: ')'</outputRendition>
    </model>
  </modelGrp>
  <modelGrp output="print">
    <model predicate="parent::choice"
      behaviour="omit"/>
    <model predicate="not(parent::choice)"
      behaviour="note">
      <param name="place" value="'foot'"/>
    </model>
  </modelGrp>
</elementSpec>
```

Example

```
<modelGrp output="print">
  <modelSequence>
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
```

```
        <model  behaviour="note">
          <param  name="place"  value="'foot'"/>
        </model>
      </modelSequence>
    </modelGrp>
```

Content model

```
<content>
 <sequence>
  <alternate minOccurs="0"
   maxOccurs="unbounded">
   <classRef key="model.identEquiv"/>
   <classRef key="model.descLike"/>
  </alternate>
  <elementRef key="outputRendition"
   minOccurs="0"/>
  <alternate minOccurs="1"
   maxOccurs="unbounded">
   <elementRef key="modelSequence"/>
   <elementRef key="model"/>
  </alternate>
 </sequence>
</content>
```

Schema Declaration

```
element modelGrp
{
   att.global.attributes,
   att.global.analytic.attributes,
   att.global.change.attributes,
   att.global.facs.attributes,
   att.global.linking.attributes,
   att.global.rendition.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   attribute useSourceRendition { text }?,
   attribute output { "web" | "print" | "plaintext" }?,
   (
      ( model.identEquiv | model.descLike )*,
      outputRendition?,
      ( modelSequence | model )+
   )
}
```

<modelSequence>

any sequence of model or <modelSequence> elements which is to be processed as a single set of actions. [*23.5.4.7. Model sequence*]
